STRONGLY BOUNDED GROUPS AND INFINITE POWERS OF
FINITE GROUPS

YVES DE CORNULIER

Abstract. We define a group as strongly bounded if every isometric action on a metric space has bounded orbits. This latter property is equivalent to the so-called uncountable strong cofinality, recently introduced by Bergman.

Our main result is that $G^I$ is strongly bounded when $G$ is a finite, perfect group and $I$ is any set. This strengthens a result of Koppelberg and Tits. We also prove that $\omega_1$-existentially closed groups are strongly bounded.

1. Introduction

Let us say that a group is strongly bounded if every isometric action on a metric space has bounded orbits.

We observe that the class of discrete, strongly bounded groups coincides with a class of groups which has recently emerged since a preprint of Bergman [Ber04], sometimes referred to as “groups with uncountable strong cofinality”, or “groups with Bergman’s Property”. This class contains no countably infinite group, but contains symmetric groups over infinite sets [Ber04], various automorphism groups of infinite structures such as 2-transitive chains [DH05], full groups of certain equivalence relations [Mil04], oligomorphic permutation groups with ample generics [KR05]; see [Ber04] for more references.

In Section 3, we prove that $\omega_1$-existentially closed groups are strongly bounded. This strengthens a result of Sabbagh [Sab75], who proved that they have cofinality $\neq \omega$.

In Section 4, we prove that if $G$ is any finite perfect group, and $I$ is any set, then $G^I$, endowed with the discrete topology, is strongly bounded. This strengthens a result of Koppelberg and Tits [KT74], who proved that this group has Serre’s Property (FA). This group has finite exponent and is locally finite, hence amenable. In contrast, all previously known infinite strongly bounded groups contain a non-abelian free subgroup.

2. Strongly bounded groups

Definition 2.1. We say that a group $G$ is strongly bounded if every isometric action of $G$ on a metric space has bounded orbits.

Remark 2.2. Let $G$ be a strongly bounded group. Then every isometric action of $G$ on a nonempty complete CAT(0) space has a fixed point; in particular, $G$ has Property (FH) and Property (FA), which mean, respectively, that every isometric action of $G$ on a Hilbert space (resp. simplicial tree) has a fixed point. This follows
from the Bruhat-Tits fixed point lemma, which states that every action of a group on a complete CAT(0) space which has a bounded orbit has a fixed point [BH, Chap. II, Corollary 2.8(1)].

It was asked in [W01] whether the equivalence between Kazhdan’s Property (T) and Property (FH), due to Delorme and Guichardet (see [BHV, Chap. 2]) holds for more general classes of groups than locally compact $\sigma$-compact groups; in particular, whether it holds for general locally compact groups.

The answer is negative, even if we restrict to discrete groups: this follows from the existence of uncountable strongly bounded groups, combined with the fact that Kazhdan’s Property (T) implies finite generation [BHV, Chap. 1].

**Definition 2.3.** We say that a group $G$ is **Cayley bounded** if, for every generating subset $U \subseteq G$, there exists some $n$ (depending on $U$) such that every element of $G$ is a product of $n$ elements of $U \cup U^{-1} \cup \{1\}$. This means every Cayley graph of $G$ is bounded.

A group $G$ is said to have cofinality $\omega$ if it can be expressed as the union of an increasing sequence of proper subgroups; otherwise it is said to have cofinality $\neq \omega$.

The combination of these two properties, sometimes referred as “uncountable strong cofinality”\(^1\), has been introduced and is extensively studied in Bergman’s preprint [Ber04]; see also [DG05]. Note that an uncountable group with cofinality $\neq \omega$ is not necessarily Cayley bounded: the free product of two uncountable groups of cofinality $\neq \omega$, or the direct product of an uncountable group of cofinality $\neq \omega$ with $\mathbb{Z}$, are obvious counterexamples. On the other hand, a Cayley bounded group with cofinality $\omega$ is announced in [Khe05].

The following result can be compared to [Ber04, Lemma 10]:

**Proposition 2.4.** A group $G$ is strongly bounded if and only if it is Cayley bounded and has cofinality $\neq \omega$.

**Proof:** Suppose that $G$ is not Cayley bounded. Let $U$ be a generating subset such that $G$ the corresponding Cayley graph is not bounded. Since $G$ acts transitively on it, it has an unbounded orbit.

Suppose that $G$ has cofinality $\omega$. Then $G$ acts on a tree with unbounded orbits [Ser, Chap I, §6.1].

Conversely, suppose that $G$ has has cofinality $\neq \omega$ and is Cayley bounded. Let $G$ act isometrically on a metric space. Let $x \in X$, let $K_n = \{ g \in G \mid d(x, gx) < n \}$, and let $H_n$ be the subgroup generated by $K_n$. Then $G = \bigcup K_n = \bigcup H_n$. Since $G$ has cofinality $\neq \omega$, $H_n = G$ for some $n$, so that $K_n$ generates $G$. Since $G$ is Cayley bounded, and since $K_n$ is symmetric, $G \subseteq (K_n)^m$ for some $m$. This easily implies that $G \subseteq K_{nm}$, so that the orbit of $x$ is bounded. $\blacksquare$

**Remark 2.5.** It follows that a countably infinite group $\Gamma$ is not strongly bounded: indeed, either $\Gamma$ has a finite generating subset, so that the corresponding Cayley graph is unbounded, or else $\Gamma$ is not finitely generated, so is an increasing union of a sequence of finitely generated subgroups, so has cofinality $\omega$.

---

\(^1\)In the literature, it is sometimes referred as “Bergman’s Property”; Bergman’s Property also sometimes refers to Cayley boundedness without cofinality assumption.
Definition 2.6. If \( G \) is a group, and \( X \subseteq G \), define
\[
\mathcal{G}(X) = X \cup \{1\} \cup \{x^{-1}, x \in X\} \cup \{xy \mid x, y \in X\}.
\]

The following proposition is immediate and is essentially contained in Lemma 10 of [Ber04].

Proposition 2.7. The group \( G \) is strongly bounded if and only if, for every increasing sequence \( (X_n) \) of subsets such that \( \bigcup_n X_n = G \) and \( \mathcal{G}(X_n) \subseteq X_{n+1} \) for all \( n \), one has \( X_n = G \) for some \( n \). ■

Remark 2.8. The first Cayley bounded groups with uncountable cofinality were constructed by Shelah [She80, Theorem 2.1]. They seem to be the only known to have a uniform bound on the diameter of Cayley graphs. They are torsion-free. These groups are highly non-explicit and their construction, which involves small cancellation theory, rests on the Axiom of Choice.

Recall that a group \( G \) is strongly bounded if and only if, for every isometric action of \( G \) on an ultrametric metric space has bounded orbits.

Remark 2.9. It is easy to observe that groups with cofinality \( \neq \omega \) also have a geometric characterization; namely, a group \( G \) has cofinality \( \neq \omega \) if and only if every isometric action of \( G \) on an ultrametric metric space has bounded orbits.

Remark 2.10. In [BHV, §2.6], it is proved that an infinite solvable group never has Property (FH) (defined in Remark 2.2). In particular, an infinite solvable group is never strongly bounded. This latter result is improved by Khelif [Khe05] who proved that an infinite solvable group is never Cayley bounded. On the other hand, it is not known whether there exist uncountable solvable groups with cofinality \( \neq \omega \).

3. \( \omega_1 \)-existentially closed groups

Recall that a group \( G \) is \( \omega_1 \)-existentially closed if every countable set of equations and inequations with coefficients in \( G \) which has a solution in a group containing \( G \), has a solution in \( G \). Sabbagh [Sab75] proved that every \( \omega_1 \)-existentially closed group has cofinality \( \neq \omega \). We give a stronger result, which has been independently noticed by Khelif [Khe05]:

Theorem 3.1. Every \( \omega_1 \)-existentially closed group \( G \) is strongly bounded.

Proof: Let \( G \) act isometrically on a nonempty metric space \( X \). Fix \( x \in X \), and define \( \ell(g) = d(gx, x) \) for all \( g \in G \). Then \( \ell \) is a length function, i.e. satisfies \( \ell(1) = 0 \) and \( \ell(gh) \leq \ell(g) + \ell(h) \) for all \( g, h \in G \). Suppose by contradiction that \( \ell \) is not bounded. For every \( n \), fix \( c_n \in G \) such that \( \ell(c_n) \geq n^2 \). Let \( C \) be the group generated by all \( c_n \). By the proof of the HNN embedding Theorem [LS, Theorem 2.1], \( C \) embeds naturally in the group
\[
\Gamma = \langle C, a, b, t ; c_n = t^{-1}b^{-n}ab^n t a^{-n}b^{-1}a^n \mid n \in \mathbb{N} \rangle,
\]
which is generated by \( a, b, t \). Since \( G \) is \( \omega_1 \)-existentially closed, there exist \( \bar{a}, \bar{b}, \bar{t} \) in \( G \) such that the group generated by \( C, \bar{a}, \bar{b}, \bar{t} \) in \( G \) such that \( \ell(c_n) \geq n^2 \). Set \( M = \max(\ell(\bar{a}), \ell(\bar{b}), \ell(\bar{t})) \). Then, since \( \ell \) is a length function and \( c_n \) can be expressed by a word of length \( 4n + 4 \) in \( a, b, t \), we get \( \ell(c_n) \leq M(4n + 4) \) for all \( n \), contradicting \( \ell(c_n) \geq n^2 \). ■
It is known [Sco51] that every group embeds in a $\omega_1$-existentially closed group. Thus, we obtain:

**Corollary 3.2.** Every group embeds in a strongly bounded group. ■

Note that this was already a consequence of the strong boundedness of symmetric groups [Ber04], but provides a better cardinality: if $|G| = \kappa$, we obtain a group of cardinality $\kappa^{\aleph_0}$ rather than $2^\kappa$.

4. Powers of finite groups

**Theorem 4.1.** Let $G$ be a finite perfect group, and $I$ a set. Then the (unrestricted) product $G^I$ is strongly bounded.

**Remark 4.2.** Conversely, if $I$ is infinite and $G$ is not perfect, then $G^I$ maps onto the direct sum $\mathbb{Z}/p\mathbb{Z}(\mathbb{N})$ for some prime $p$, so has cofinality $\omega$ and is not Cayley bounded, as we see by taking as generating subset the canonical basis of $\mathbb{Z}/p\mathbb{Z}(\mathbb{N})$.

**Remark 4.3.** By Proposition 4.4, every Cayley graph of $G^I$ is bounded. If $I$ is infinite and $G \neq 1$, one can ask whether we can choose a bound which does not depend on the choice of the Cayley graph. The answer is negative: indeed, for all $n \in \mathbb{N}$, observe that the Cayley graph of $G^n$ has diameter exactly $n$ if we choose the union of all factors as generating set. By taking a morphism of $G^I$ onto $G^n$ and taking the preimage of this generating set, we obtain a Cayley graph for $G^I$ whose diameter is exactly $n$.

Our remaining task is to prove Theorem 4.1. The proof is an adequate modification of the original proof of the (weaker) result of Koppelberg and Tits [KT74], which states that $G^I$ has cofinality $\neq \omega$.

If $A$ is a ring with unity, and $X \subseteq A$, define

$$R(X) = X \cup \{-1, 0, 1\} \cup \{x + y \mid x, y \in X\} \cup \{xy \mid x, y \in X\}.$$ 

It is clear that $\bigcup_{n \in \mathbb{N}} R^n(X)$ is the subring generated by $X$.

Recall that a Boolean algebra is an associative ring with unity which satisfies $x^2 = x$ for all $x$. Such a ring has characteristic 2 (since $2 = 2^2 - 2$) and is commutative (since $xy - yx = (x + y)^2 - (x + y)$). The ring $\mathbb{Z}/2\mathbb{Z}$ is a Boolean algebra, and so are all its powers $\mathbb{Z}/2\mathbb{Z}^E = \mathcal{P}(E)$, for any set $E$.

**Proposition 4.4.** Let $E$ be a set, and $(\mathcal{X}_i)_{i \in \mathbb{N}}$ an increasing sequence of subsets of $\mathcal{P}(E)$. Suppose that $R(\mathcal{X}_i) \subseteq \mathcal{X}_{i+1}$ for all $i$. Suppose that $\mathcal{P}(E) = \bigcup_{i \in \mathbb{N}} \mathcal{X}_i$. Then $\mathcal{P}(E) = \mathcal{X}_i$ for some $i$.

**Remark 4.5.** 1) We could have defined, in analogy of Definition 2.3, the notion of strongly bounded ring (although the terminology “uncountable strong cofinality” seems more appropriate in this context). Then Proposition 4.4 can be stated as: if $E$ is infinite, the ring $\mathcal{P}(E) = \mathbb{Z}/2\mathbb{Z}^E$ is strongly bounded. If $E$ is infinite, note that, as an additive group, it maps onto $\mathbb{Z}/2\mathbb{Z}(\mathbb{N})$, so has cofinality $\omega$ and is not Cayley bounded.

**Proof** of Proposition 4.4. Suppose the contrary. If $X \subseteq E$, denote by $\mathcal{P}(X)$ the power set of $X$, and view it as a subset of $\mathcal{P}(E)$. Define $\mathcal{L} = \{X \in \mathcal{P}(E) \mid \forall i, \mathcal{P}(X) \not\subseteq \mathcal{X}_i\}$. The assumption is then: $E \in \mathcal{L}$.
Observation: if \( X \in \mathcal{L} \) and \( X' \subseteq X \), then either \( X' \) or \( X - X' \) belongs to \( \mathcal{L} \). Indeed, otherwise, some \( \mathcal{X}_i \) would contain \( \mathcal{P}(X') \) and \( \mathcal{P}(X - X') \), and then \( \mathcal{X}_{i+1} \) would contain \( \mathcal{P}(X) \).

We define inductively a decreasing sequence of subsets \( B_i \in \mathcal{L} \), and a non-decreasing sequence of integers \((n_i)\) by:

\[
B_0 = E; \\
C_i = \inf\{ t \mid B_i \in \mathcal{X}_i \}; \\
B_{i+1}' \subseteq B_i \quad \text{and} \quad B_{i+1} \notin \mathcal{X}_{n_{i+1}}; \\
B_{i+1} = \begin{cases} B_{i+1}' \quad &\text{if } B_{i+1}' \in \mathcal{L}, \\ B_i - B_{i+1}' \quad &\text{otherwise.} \end{cases}
\]

Define also \( C_i = B_i - B_{i+1} \). The sets \( C_i \) are pairwise disjoint.

**Fact 4.6.** For all \( i, B_i \notin \mathcal{X}_{n_i} \) and \( C_i \notin \mathcal{X}_{n_i} \).

**Proof:** Observe that \( \{B_{i+1}, C_i\} = \{B_{i+1}', B_i - B_{i+1}'\} \). We already know \( B_{i+1}' \notin \mathcal{X}_{n_{i+1}} \), so it suffices to check \( B_i - B_{i+1}' \notin \mathcal{X}_{n_i} \). Otherwise, \( B_{i+1}' = B_i - (B_i - B_{i+1}') \in \mathcal{R}(B_i, B_i - B_{i+1}') \subseteq \mathcal{R}(\mathcal{X}_{n_i}) \subseteq \mathcal{X}_{n+1} \), which is a contradiction. \( \square \)

This fact implies that the sequence \((n_i)\) is strictly increasing. We now use a diagonal argument. Let \( (N_j)_{j \in \mathbb{N}} \) be a partition of \( \mathbb{N} \) into infinite subsets. Set \( D_j = \bigcup_{i \in N_j} C_i \) and \( m_j = \inf\{ t \mid D_j \in \mathcal{X}_i \} \), and let \( l_j \) be an element of \( N_j \) such that \( l_j > \max(m_j, j) \).

Set \( X = \bigcup_{j} C_{l_j} \). For all \( j, D_j \cap X = C_{l_j} \notin \mathcal{X}_{l_j} \). On the other hand, \( D_j \in \mathcal{X}_{m_j} \subseteq \mathcal{X}_{l_{j-1}} \) since \( l_j \geq m_j + 1 \). This implies \( X \notin \mathcal{X}_{l_j-1} \supseteq \mathcal{X}_l \) for all \( j \), contradicting \( \mathcal{P}(E) = \bigcup_{i \in \mathbb{N}} \mathcal{X}_i \).

The following corollary, of independent interest, was suggested to me by Romain Tessera.

**Corollary 4.7.** Let \( A \) be a finite ring with unity (but not necessarily associative or commutative). Let \( E \) be a set, and \( (\mathcal{X}_i)_{i \in \mathbb{N}} \) an increasing sequence of subsets of \( A^E \). Suppose that \( \mathcal{R}(\mathcal{X}_i) \subseteq \mathcal{X}_{i+1} \) for all \( i \). Suppose that \( A^E = \bigcup_{i \in \mathbb{N}} \mathcal{X}_i \). Then \( A^E = \mathcal{X}_i \) for some \( i \).

**Proof:** By reindexing, we can suppose that \( \mathcal{X}_0 \) contains the constants. Write \( \mathcal{X}_i = \{ J \subseteq E \mid J \in \mathcal{X}_{3i} \} \). If \( J, K \in \mathcal{X}_i \), \( J \cap K = 1 \), \( J \cup K = 1 \), \( J \cap (K + 1) = 1 \), \( J \cup (K + 1) = 1 \), \( K \in \mathcal{X}_{3i+1} \), so that \( J \in \mathcal{X}_{i+1} \), and \( J \cap K = 1 \). By Proposition 4.4, \( \mathcal{X}_n = \mathcal{P}(E) \) for some \( n \). It is then clear that \( A^E = \mathcal{X}_n \) for some \( n \) (say, \( n = 3m + 1 + \lceil \log_2 |A| \rceil \)). \( \blacksquare \)

If \( A \) is a Boolean algebra, and \( X \subseteq A \), we define

\[
\mathcal{D}(X) = X \cup \{0, 1\} \cup \{ x + y \mid x, y \in X \} \quad \text{such that} \quad xy = 0 \cup \{ xy \mid x, y \in X \}. \\
\mathcal{I}_k(X) = \{ x_1, x_2, \ldots, x_k \} \quad \text{such that} \quad x_i x_j = 0 \, \forall i \neq j. \\
\mathcal{V}_k(X) = \{ x_1 + x_2 + \ldots, x_k \} \quad \text{such that} \quad x_i x_j = 0 \, \forall i \neq j.
\]

The following lemma contains some immediate facts which will be useful in the proof of the main result.
Lemma 4.8. Let $A$ be a Boolean algebra, and $X \subseteq A$ a symmetric subset (i.e. closed under $x \mapsto 1-x$) such that $0 \in X$. Then, for all $n \geq 0$,

1) $\mathcal{R}^n(X) \subseteq \mathcal{D}^{2n}(X)$, and

2) $\mathcal{D}^n(X) \subseteq \mathcal{V}_{2^n}(\mathcal{I}_{2^n}(X))$.

Proof: 1) It suffices to prove $\mathcal{R}(X) \subseteq \mathcal{D}^2(X)$. Then the statement of the lemma follows by induction. Let $u \in \mathcal{R}(X)$. If $u \not\in \mathcal{D}(X)$, then $u = x+y$ for some $x, y \in X$. Then $u = (1-x)y + (1-y)x \in \mathcal{D}^2(X)$.

2) Is an immediate induction. ■

Definition 4.9 ([KT74]). Take $n \in \mathbb{N}$, and let $G$ be a group. Consider the set of functions $G^n \to G$; this is a group under pointwise multiplication. The elements $m(g_1, \ldots, g_n)$ in the subgroup generated by the constants and the canonical projections are called monomials. Such a monomial is homogeneous if $m(g_1, \ldots, g_n) = 1$ whenever at least one $g_i$ is equal to 1.

Lemma 4.10 ([KT74]). Let $G$ be a finite group which is not nilpotent. Then there exist $a \in G$, $b \in G \setminus \{1\}$, and a homogeneous monomial $f : G^2 \to G$, such that $f(a, b) = b$.

The proof can be found in [KT74], but, for the convenience of the reader, we have included the proof from [KT74] in the (provisional) Appendix below.

Remark 4.11. If $G$ is a group, and $f(x_1, \ldots, x_n)$ is a homogeneous monomial with $n \geq 2$, then $m(g_1, \ldots, g_n) = 1$ whenever at least one $g_i$ is central: indeed, we can then write, for all $x_1, \ldots, x_n$ with $x_i$ central, $m(x_1, \ldots, x_i, \ldots, x_n) = m'(x_1, \ldots, \hat{x}_i, \ldots, x_n)x_i^k$. By homogeneity in $x_i$, $m'(x_1, \ldots, \hat{x}_i, \ldots, x_n) = 1$, and we conclude by homogeneity in $x_j$ for any $j \neq i$.

Accordingly, if $(C_\alpha)$ denotes the (transfinite) ascending central series of $G$, an immediate induction on $\alpha$ shows that if $f(a, b) = b$ for some homogeneous monomial $f$, $a \in G$ and $b \in C_\alpha$, then $b = 1$. In particular, if $G$ is nilpotent (or even residually nilpotent), then the conclusion of Lemma 4.10 is always false.

Lemma 4.12. Let $G$ be a finite group, $I$ a set, and $H = G^I$. Suppose that $f(a, b) = b$ for some $a, b \in G$, and some homogeneous monomial $f$, and let $N$ be the normal subgroup of $G$ generated by $b$. Let $(X_m)$ be an increasing sequence of subsets of $H$ such that $g(X_m) \subseteq X_{m+1}$ (see Definition 2.6), and $\bigcup X_m = H$. Then $N^I \subseteq X_m$ for $m$ big enough.

Proof: Suppose the contrary. If $x \in G$ and $J \subseteq I$, denote by $x_J$ the element of $G^I$ defined by $x_J(i) = x$ if $i \in J$ and $x_J(i) = 1$ if $i \not\in J$.

Denote by $\tilde{f} = f^I$ the corresponding homogeneous monomial: $H^2 \to H$. Upon extracting, we can suppose that all $c_J, c \in G$, are contained in $X_0$. In particular, the “constants” which appear in $f$ are all contained in $X_0$.

Hence we have, for all $m$, $f(X_m, X_m) \subseteq X_{m+d}$, where $d$ depends only on the length of $f$. For $J, K \subseteq I$, we have the following relations:

\begin{align}
(4.1) & \quad a_I a_J^{-1} = a_{I-J}, \\
(4.2) & \quad \tilde{f}(a_{I}, b_K) = b_{I \cap K}, \\
(4.3) & \quad \tilde{f}(a_J, b_I) = b_J,
\end{align}
(4.4) If \( J \cap K = \emptyset \), \( b_J, b_K = b_{J \cup K} \).

For all \( m \), write \( \mathcal{W}_m = \{ J \in \mathcal{P}(I) \mid a_J \in X_m \} \), and let \( \mathcal{A}_m \) be the Boolean algebra generated by \( \mathcal{W}_m \). Then \( \bigcup_m \mathcal{A}_m = \mathcal{P}(I) \). By Proposition 4.4, there exists some \( M \) such that \( \mathcal{A}_M = \mathcal{P}(I) \). Set \( \mathcal{X}_n = \mathcal{R}^n(\mathcal{W}_M) \). Then, since \( \mathcal{A}_M = \mathcal{P}(I) \), \( \bigcup_n \mathcal{X}_n = \mathcal{P}(I) \). Again by Proposition 4.4, there exists some \( N \) such that \( \mathcal{X}_N = \mathcal{P}(I) \). So, by 1) of Lemma 4.8, we get

\[
\mathcal{D}^2N(\mathcal{W}_M) = \mathcal{P}(I).
\]

Define, for all \( m \), \( \mathcal{B}_m = \{ J \in \mathcal{P}(I) \mid b_J \in X_m \} \). Then from (4.3) we get: \( \mathcal{W}_m \subseteq \mathcal{B}_{m+d} \); from (4.2) we get: if \( J \in \mathcal{W}_m \) and \( K \in \mathcal{B}_m \), then \( J \cap K \in \mathcal{B}_{m+d} \); and from (4.4) we get: if \( J, K \in \mathcal{B}_m \) and \( J \cap K = \emptyset \), then \( J \cup K \in \mathcal{B}_{m+1} \).

By induction, we deduce \( \mathcal{B}_k(\mathcal{W}_m) \subseteq \mathcal{B}_{m+kd} \) for all \( k \), and \( \mathcal{B}_k(\mathcal{B}_m) \subseteq \mathcal{B}_{m+k} \) for all \( k \). Composing, we obtain \( \mathcal{V}_k(\mathcal{B}_m) \subseteq \mathcal{V}_k(\mathcal{W}_m) \subseteq \mathcal{V}_k(\mathcal{B}_m) \subseteq \mathcal{B}_{m+kd} \). By 2) of Lemma 4.8, we get \( \mathcal{D}^n(\mathcal{B}_m) \subseteq \mathcal{B}_{m+2^dn+2^mn} \). Hence, using (4.5), we obtain \( \mathcal{P}(I) = \mathcal{Y}_D \), where \( D = M + 4^N d + 2^{4N} \).

Let \( B \) denote the subgroup generated by \( b \), so that \( N \) is the normal subgroup generated by \( B \). Let \( r \) be the order of \( b \). Then \( B^I \) is contained in \( X_{D+r} \). Moreover, there exists \( R \) such that every element of \( N \) is the product of \( R \) conjugates of elements of \( B \). Then, using that \( c_I \in X_0 \) for all \( c \in G \), \( N^I \) is contained in \( X_{D+r+3R} \). ■

Theorem 4.13. Let \( G \) be a finite group, and let \( N \) the last term of its descending central series (so that \( [G, N] = N \)). Let \( I \) be any set, and set \( H = G^I \). Let \( (X_m) \) be an increasing sequence of subsets of \( H \) such that \( G(X_m) \subseteq X_{m+1} \) and \( \bigcup X_m = H \). Then \( N^I \subseteq X_m \) for \( m \) big enough.

Proof: Let \( G \) be a counterexample with \( |G| \) minimal. Let \( W \) be a normal subgroup of \( G \) such that \( W^I \) is contained in \( X_m \) for large \( m \), and which is maximal for this property. Since \( G \) is a counterexample, \( N \not\subseteq W \). Hence \( G/W \) is not nilpotent, and is another counterexample, so that, by minimality, \( W = \{1\} \). Since \( G \) is not nilpotent, there exists, by Lemma 4.10, \( a \in G, b \in G - \{1\} \), and a homogeneous monomial \( f : G^2 \rightarrow G \), such that \( f(a, b) = b \). So, if \( M \) is the normal subgroup generated by \( b \), \( M^I \) is contained, by Lemma 4.12, in \( X_i \) for large \( i \). This contradicts the maximality of \( W = \{1\} \). ■

In view of Proposition 2.7, Theorem 4.1 immediately follows from Theorem 4.13. Theorem 4.1 has been independently proved by Khelif [Khe05], who also proves Proposition 4.4, but concludes by another method.

Question 4.14. Let \( G \) be a finite group, and \( N \) a subgroup of \( G \) which satisfies the conclusion of Theorem 4.13 (\( I \) being infinite). Is it true that, conversely, \( N \) must be contained in the last term of the descending central series of \( G \)? We conjecture that the answer is positive, but the only thing we know is that \( N \) must be contained in the derived subgroup of \( G \).

Remark 4.15. We could have introduced a relative definition: if \( G \) is a group and \( X \subseteq G \) is a subset, we say that the pair \( (G, X) \) is strongly bounded if, for every isometric action of \( G \) on any metric space \( M \) and every \( m \in M \), then the “\( X \)-orbit” \( Xm \) is bounded. Note that \( G \) is strongly bounded if only if the pair \( (G, G) \) is strongly bounded. Proposition 2.7 generalizes as: the pair \( (G, X) \) is
strongly bounded if and only if for every sequence \((X_n)\) of subsets of \(G\) such that 
\[ \bigcup_n X_n = G \text{ and } G(X_n) \subseteq X_{n+1} \text{ for all } n, \] 
one has \(X_n \supseteq X\) for some \(n\).

Theorem 4.13 is actually stronger than Theorem 4.1: it states that if \(G\) is a finite group, if \(N\) is the last term of its descending central series, and if \(I\) is any set, then the pair \((G', N')\) is strongly bounded. This provides non-trivial strongly bounded pairs of solvable groups (trivial pairs are those pairs \((G, X)\) with \(X\) finite); compare Remark 2.10 and Question 4.14.

**Question 4.16.** We do not assume the continuum hypothesis. Does there exist a strongly bounded group with cardinality \(\aleph_1\)?

It seems likely that a variation of the argument in [She80] might provide examples.

**Question 4.17.** Let \((G_n)\) be a sequence of finite perfect groups. When is the product \(\prod_{n \in \mathbb{N}} G_n\) strongly bounded?

It follows from Theorem 4.1 that if the groups \(G_n\) have bounded order, then \(\prod_{n \in \mathbb{N}} G_n\) is strongly bounded. If all \(G_n\) are simple, Saxl, Shelah and Thomas prove [SST96, Theorems 1.7 and 1.9] that \(\prod_{n \in \mathbb{N}} G_n\) has cofinality \(\neq \omega\) if and only if there does not exist a fixed (possibly twisted) Lie type \(L\), a sequence \((n_i)\) and a sequence \((q_i)\) of prime powers tending to infinity, such that \(G_{n_i} \simeq L(q_i)\) for all \(i\). Does this still characterize infinite strongly bounded products of non-abelian finite simple groups?

**Appendix A. Proof of Lemma 4.10**

This Appendix is added for the convenience of the reader. It is dropped in the published version.

**Lemma A.1** ([KT74]). Let \(G\) be a group, \(g \in G\), and \(g'\) an element of the subgroup generated by the conjugates of \(g\). Then there exists a homogeneous monomial \(f : G \to G\) such that \(f(g) = g'\).

**Proof:** Write \(g' = \prod c_i g^\alpha_i c_i^{-1}\). Then \(x \mapsto \prod c_i x^\alpha_i c_i^{-1}\) is a homogeneous monomial and \(f(g) = g'\). ■

**Lemma A.2.** Let \(G\) be a finitely generated group. Suppose that \(G\) is not nilpotent. Then there exists \(a \in G\) such that the normal subgroup of \(G\) generated by \(a\) is not nilpotent.

**Proof:** Fix a finite generating subset \(S\) of \(G\). For every \(s \in S\), denote by \(N_s\) the normal subgroup of \(G\) generated by \(s\). Since finitely many nilpotent normal subgroups generate a nilpotent subgroup, it immediately follows that if all \(N_s\) are nilpotent, then \(G\) is nilpotent. ■

**Proof** of Lemma 4.10. We reproduce the proof from [KT74]. Let \(G\) be a finite group which is not nilpotent. We must show that there exist \(a \in G\), \(b \in G - \{1\}\), and a homogeneous monomial \(f : G^2 \to G\), such that \(f(a, b) = b\).

Take \(a\) as in Lemma A.2, and \(A\) the normal subgroup generated by \(a\). Let \(A_1\) be the upper term of the ascending central series of \(A\). We define inductively the sequences \((a_i)_{i \in \mathbb{N}}\) and \((b_i)_{i \in \mathbb{N}}\) such that 
\[ b_i \in A - A_1, \quad a_i \in A \quad \text{and} \quad b_{i+1} = [a_i, b_i] \in A - A_1. \]
Since $G$ is finite, there exist integers $m, m'$ such that $m < m'$ and $b_m = b_{m'}$. Set $b = b_m$, and for all $i$, choose, using Lemma A.1, a homogeneous monomial $f_i$ such that $f_i(a) = a_i$. Then the monomial

$$f : (x, y) \mapsto [f_{m'-1}(x), [f_{m'-2}(x), \ldots, [f_m(x), y], \ldots]]$$

satisfies $f(a, b) = b$. ■

Appendix B. Groups with cardinality $\aleph_1$ and Property (FH)

This appendix is dropped in the published version.

Proposition B.1. Let $G$ be a countable group. Then $G$ embeds in a group of cardinality $\aleph_1$ with Property (FH).

The proof rests on two ingredients.

Theorem B.2 (Delzant). If $G$ is any countable group, then $G$ can be embedded in a group with Property (T).

Sketch of proof: this is a corollary of the following result, first claimed by Gromov\(^2\), and subsequently independently proved by Delzant\(^3\) and Olshanskii\(^4\): if $H$ is any non-elementary word hyperbolic group, then $H$ is SQ-universal, that is, every countable group embeds in a quotient of $H$. Thus, the result follows from the stability of Property (T) by quotients, and the existence of non-elementary word hyperbolic groups with Property (T); for instance, uniform lattices in $\text{Sp}(n, 1)$, $n \geq 2$ (see [HV]). ■

Let $C$ be any class of metric spaces, let $G$ be a group. Say that $G$ has Property (FC) if for every isometric action of $G$ on a space $X \in C$, all orbits are bounded. For instance, if $C$ is the class of all Hilbert spaces, then we get Property (FH).

Proposition B.3. Let $G$ be a group in which every countable subset is contained in a subgroup with Property (FC). Then $G$ has Property (FC).

Proof: Let us take an affine isometric action of $G$ on a metric space $X \in C$, and let us show that it has bounded orbits. Otherwise, there exists $x \in X$, and a sequence $(g_n)$ in $G$ such that $d(g_n x, x) \to \infty$. Let $H$ be a subgroup of $G$ with Property (FC) containing all $g_n$. Since $Hx$ is not bounded, we have a contradiction. ■

Proof of Proposition B.1. We make a standard transfinite induction on $\omega_1$ (as in [Sab75]), using Theorem B.2. For every countable group $\Gamma$, choose a proper embedding of $\Gamma$ into a group $F(\Gamma)$ with Property (T) (necessarily finitely generated). Fix $G_0 = G$, $G_{\alpha+1} = F(G_\alpha)$ for every $\alpha < \omega_1$, and $G_\lambda = \lim_{\beta < \lambda} G_\beta$ for every limit ordinal $\lambda \leq \omega_1$. It follows from Proposition B.3 that $G_{\omega_1}$ has Property (FH). Since all embeddings $G_\alpha \to G_{\alpha+1}$ are proper, $G_{\omega_1}$ is not countable, hence has cardinality $\aleph_1$. ■

Acknowledgments. I thank Bachir Bekka, who has suggested to me to show that the groups studied in [KT74] have Property (FH). I am grateful to George

M. Bergman, David Madore, Romain Tessera and Alain Valette for their useful corrections and comments.
