We decrease the temperature to reach a **Bose-Einstein condensate (BEC)**.

Ligar-shape BEC

10 000 atoms

$L = 200 \mu\text{m}$

$\sigma = 5 \mu\text{m}$

- Destructive measurement,
  - We prepare a BEC in 10 s.
- Important to have statistics  $\langle \hat{P} \rangle, \langle \hat{P}^2 \rangle, \langle \hat{X} \rangle, \langle \hat{X}^2 \rangle, \dots$

In the experiment:

$T = 40 \text{ nK}$

(0 K = -273.15 °C)

$$\begin{cases} v_x = X/T & p = mv = \hbar k \\ v_y = Y/T & \hbar \text{ Planck constant} \\ v_z = gT/2 - H/T & m \text{ mass} \end{cases}$$

|                       |                        |                        |                         |                      |                         |                        |                        |                         |                        |                         |                         |                       |                        |                          |                         |                        |                        |                       |                     |                      |                   |                      |                   |

- Does parametric amplification of quasi-particles in a BEC lead to an entangled state?
- How these quasi-particles thermalize?

## ① Theoretical considerations

- a) Parametric amplification & motivations
- b) Parametric amplification of quasi-particles in a Bose-Einstein condensate.

## ② Experimental result

- a) Growth of the quasi-particle number
- b) Correlations & entanglement of the two-mode state.

# Parametric excitation of an elongated BEC

Perturbative approach: Bogoliubov 1D

- $\hat{\Psi} \sim \frac{\sqrt{n_1}}{\sigma} e^{-r^2/2\sigma^2} [1 + \hat{\phi}(z)]$
- $n_1 = N/L$
- $g_1 \sim 1/\sigma^2$  1D effective interaction
- We study collective excitations:
  - $\hat{b}_k$  annihilates a quasi-particle at  $k$
  - $\hat{b}_k^\dagger$  creates a quasi-particle at  $k$

- $\hat{b}_k$  diagonalizes the Hamiltonian

$$i\hbar\partial_t \hat{b}_k = \omega_k \hat{b}_k + i \frac{\dot{\omega}_k}{2\omega_k} \hat{b}_{-k}^\dagger$$

- Dispersion relation

$$\omega_k = \sqrt{2g_1 n_1 \frac{\hbar^2 k^2}{2m} + \left( \frac{\hbar^2 k^2}{2m} \right)^2}$$

$\nearrow g_1$  depends on  $\sigma(t)$

$\sigma$  oscillates at  $\Omega$  parametrically excites quasi-particles by pairs with  $\omega_k = \Omega/2$ .

TMSv if zero temperature,

$$|\phi\rangle \sim \sum_i \alpha^i |i, i\rangle_{-k, k}$$

Mode -k  
Mode +k

i.e. an entangled state.

## Theoretical cheatsheet

Carusotto *et al.* EPJD (2010),  
Busch *et al.* PRA (2014),  
Robertson *et al.* PRD (2017,2018),  
Micheli & Robertson, PRD (2022)

Perturbative approach (linear equation of motion)

Excitation at  $\Omega$  produce opposite moment quasi-particles with frequency  $\omega_k = \Omega/2$

Exponential growth of the quasi-particle number trigger by fluctuations

Entanglement of the  $(k, -k)$  state only if the temperature is small enough.

Non-linear effects lead to decoherence and thermalization.

## Experimental challenges

- Observation of quasi-particle creation,
- Quasi-particle frequency is  $\omega_k = \Omega/2$ ,
- Study the exponential creation process,
- Observation of correlations, non-classical effects and/or entanglement.

Jaskula *et al.* PRL (2012)

## ① Theoretical considerations

- a) Parametric amplification & motivations
- b) Parametric amplification of quasi-particles in a Bose-Einstein condensate.

## ② Experimental result

- a) Growth of the quasi-particle number
- b) Correlations & entanglement of the two-mode state.

We excite the breathing mode of the BEC.

Jaskula *et al* PRL (2012)

- ✓ Breathing mode keeps low temperature,
- ✓ Small excitation to stay in perturbative regime.

We count the mean number of atoms  $n_k, n_{-k}$

# Exponential growth of the phonon number

Fit function:

Theoretical quasi-particle  
growth dynamics

$$n_k(t) = \left[ n_k^{(in)} + \underbrace{\left( n_k^{(in)} + n_{-k}^{(in)} + 1 \right)}_{\text{thermal vacuum}} \sinh^2(G_k \Delta t / 2) \right]$$

Growth rate

Fluctuations

Empirical oscillation

Oscillation  
amplitude

Quasi-particle  
frequency

# Measuring the growth rate

- ✓ We fit the growth rate  $G_k^{(exp)}$  from the population growth.

Measure the theoretical growth rate from the BEC

$$G_k^{(th)} = \frac{\omega_k}{2} \frac{\Delta g_1 / g_1}{1 + k^2 \xi^2}$$

healing length

Busch *et al.* PRA (2014)

Higher-order quasi-particle interactions decrease the growth rate  $\Gamma_k = G_k^{(th)} - G_k^{(exp)}$ .

The slowing of the growth (*i.e.* the decay rate) we measure is compatible with theoretical predictions\*.

\* Within not so small error bars.

# Exponential growth of the phonon number

Fit function:

Theoretical quasi-particle  
growth dynamics

$$n_k(t) = \left[ n_k^{(in)} + \left( \underbrace{n_k^{(in)}}_{\text{thermal}} + \underbrace{n_{-k}^{(in)}}_{\text{vacuum}} + 1 \right) \sinh^2(G_k \Delta t / 2) \right]$$

Growth rate

Fluctuations

Empirical oscillation

$$\times (1 + A_k \cos(2\omega_k \Delta t + \varphi))$$

Oscillation  
amplitude

Quasi-particle  
frequency

Such oscillation in the quasi-particle growth is not expected...

We measure atoms and not quasi-particles :  
how does the *collective excitations* state  $\hat{b}_k$   
maps to the *atomic* state  $\hat{\phi}_k$ ?

$$\hat{\phi}_k \sim \hat{b}_k + \hat{b}_{-k}^\dagger$$

The detected atom number:

$$n_k = \langle \hat{\phi}_k^\dagger \hat{\phi}_k \rangle \sim \underbrace{\langle \hat{b}_k^\dagger \hat{b}_k \rangle}_{\text{Cool}} + \dots + \underbrace{|\langle \hat{b}_{-k} \hat{b}_k \rangle| \cos 2\omega_k \Delta t}_{\text{Not cool}}$$

**BUT**

$$\hat{b}_k \Rightarrow \hat{\phi}_k^{\text{det}}$$

if  $\omega_k$  changes adiabatically w.r.t.  $\omega_k^{-1}$ .

$$\omega_k = \sqrt{2g_1 n_1 \frac{\hbar^2 k^2}{2m} + \left( \frac{\hbar^2 k^2}{2m} \right)^2}$$

$g_1$  depends on  $\sigma(t)$

We turn off slowly the laser power  
so that  $\sigma$  changes slowly.

## ① Theoretical considerations

- a) Parametric amplification & motivations
- b) Parametric amplification of quasi-particles in a Bose-Einstein condensate.

## ② Experimental result

- a) Growth of the quasi-particle number
- b) Correlations & entanglement of the two-mode state.

# Correlations and relative number squeezing

We study correlations between  $\hat{n}_{-k}$  &  $\hat{n}_k$ .

# Correlations and relative number squeezing

We study correlations between  $\hat{n}_{-k}$  &  $\hat{n}_k$ .

We observe relative number squeezing

$$\frac{\text{Var}(n_k - n_{-k})}{n_k + n_{-k}} = 0.91(4) < 1$$

Non-classical effect!

But how to witness entanglement ?

# How to witness entanglement?

$\hat{\phi}_k$  annihilation  
operator for  
an atom

What we need:

$$\underbrace{n_k n_{-k}}_{\text{Populations}} < \underbrace{|\langle \hat{\phi}_k \hat{\phi}_{-k} \rangle|^2}_{\text{Anomalous correlation}} \Rightarrow \text{entanglement}$$

What we measure:

- Populations:  $n_k = \langle \hat{\phi}_k^\dagger \hat{\phi}_k \rangle$ ,  $n_{-k} = \langle \hat{\phi}_{-k}^\dagger \hat{\phi}_{-k} \rangle$
- **N-body** correlation functions

$$G_{k,-k}^{(2)} = \langle \hat{\phi}_{-k}^\dagger \hat{\phi}_k^\dagger \hat{\phi}_{-k} \hat{\phi}_k \rangle,$$

$$G_{k,-k}^{(4)} = \langle \hat{\phi}_{-k}^{\dagger 2} \hat{\phi}_k^{\dagger 2} \hat{\phi}_{-k}^2 \hat{\phi}_k^2 \rangle,$$

*We need to connect **N-body** correlation functions to **field** correlation functions.*

## Theoretical consideration

- weakly interacting gas,
  - linear equation of motion,
  - small depletion (1/10 000) to stay perturbative.
- } Gaussian hypothesis
- Robertson *et al* PRD (2018)

Any correlation functions solely depend on correlation functions between one- and two-field operators  $\langle \hat{\phi}_q \rangle$ ,  $\langle \hat{\phi}_q \hat{\phi}_k^{(\dagger)} \rangle$ .

*Gaussian hypothesis*

If  $\langle \hat{\phi}_k \rangle = \langle \hat{\phi}_{-k} \rangle = 0$ , the normalized cross two-body correlation function is given by:

$$g_{-k,k}^{(2)} = \frac{G_{-k,k}^{(2)}}{n_k n_{-k}} = 1 + \underbrace{\frac{|\langle \hat{\phi}_k \hat{\phi}_{-k} \rangle|^2}{n_k n_{-k}}}_{\text{Anomalous correlation}} + \underbrace{\frac{|\langle \hat{\phi}_k^\dagger \hat{\phi}_{-k} \rangle|^2}{n_k n_{-k}}}_{\text{Coherence}}$$

$$n_k n_{-k} < |\langle \hat{\phi}_k \hat{\phi}_{-k} \rangle|^2 \Rightarrow \text{entanglement}$$

Hillery & Zubairy PRL (2006)

We can connect N-body to two-field correlation functions!

*Easily checked!*

$$\text{if } \begin{cases} \langle \hat{\phi}_k \rangle = \langle \hat{\phi}_{-k} \rangle = 0 \\ \langle \hat{\phi}_k^2 \rangle = \langle \hat{\phi}_{-k}^2 \rangle = 0 \\ \langle \hat{\phi}_k^\dagger \hat{\phi}_{-k} \rangle = 0 \end{cases}$$

$$g_{-k,k}^{(2)} > 2 \Leftrightarrow \text{entanglement}$$

Busch & Parentani, PRD (2014)

$$g_{-k,k}^{(2)} = \frac{G_{-k,k}^{(2)}}{n_k n_{-k}} = 1 + \underbrace{\frac{|\langle \hat{\phi}_k \hat{\phi}_{-k} \rangle|^2}{n_k n_{-k}}}_{\text{Anomalous correlation}} + \underbrace{\frac{|\langle \hat{\phi}_k^\dagger \hat{\phi}_{-k} \rangle|^2}{n_k n_{-k}}}_{\text{Coherence}}$$

$$n_k n_{-k} < |\langle \hat{\phi}_k \hat{\phi}_{-k} \rangle|^2 \Rightarrow \text{entanglement}$$

Hillery & Zubairy PRL (2006)

## $g^{(2)}/g^{(4)}$ entanglement criterion

For a two-mode thermal Gaussian state\*, the measurement of the  $n_k, n_{-k}, g_{-k,k}^{(2)}$  &  $g_{-k,k}^{(4)}$  quantifies entanglement.

## $g^{(2)}$ entanglement witness

For a two-mode thermal Gaussian state\*, the measurement of  $n_k, n_{-k}$  &  $g_{-k,k}^{(2)}$  are sufficient to detect entanglement.

$$* \begin{cases} \langle \hat{\phi}_k \rangle = \langle \hat{\phi}_{-k} \rangle = 0 \\ \langle \hat{\phi}_k^2 \rangle = \langle \hat{\phi}_{-k}^2 \rangle = 0 \end{cases}$$

Let's check on the experimental side!

# Measuring the two- and four-body correlation function

Map of  $g^{(2)}(v_{z,1}, v_{z,2}) = \frac{\langle \hat{n}_1 \hat{n}_2 \rangle}{\langle \hat{n}_1 \rangle \langle \hat{n}_2 \rangle}$

Bosonic bunching:

- $g_{-k,-k}^{(2)} = 1.94(9)$
- $g_{k,k}^{(2)} = 1.98(12)$

As expected for thermal statistics!

We measure  $g_{k,-k}^{(2)} = 2.2(1)$

$g^{(2)}$  entanglement witness

The entanglement witness reveals  
that the state is entangled!

Parametric amplification of quasi-particles  
in a BEC leads to an entangled state.

## Experimental challenges

- Fast production of a stable ultra-cold BEC,
- Observation of really all quasi-particles,
- Quasi-particle frequency is  $\omega_k = \Omega/2$ ,
- **Study the exponential creation process,**
- **Slow-down of the growth in agreement with theoretical predictions,**
- **Observation of entanglement between two modes of opposite momentum massive particles.**

These results

Experimental input

## Entanglement evolution

How entanglement evolves, disappear? Study thermalization of quasi-particles.

## Higher order excitations

Higher order resonance with rich correlations properties.

## Entanglement evolution

How entanglement evolves, disappear? Study thermalization of quasi-particles.

## Higher order excitations

Higher order resonance with rich correlations properties.

## Beyond the Gaussian hypothesis

Violation of Bell inequalities

- Need for 2x2 modes,
- Low population regime.

En présence de mes pairs.

Parvenu à l'issue de mon doctorat en physique, et ayant ainsi pratiqué, dans ma quête du savoir, l'exercice d'une recherche scientifique exigeante, en cultivant la rigueur intellectuelle, la réflexivité éthique et dans le respect des principes de l'intégrité scientifique, je m'engage, pour ce qui dépendra de moi, dans la suite de ma carrière professionnelle quel qu'en soit le secteur ou le domaine d'activité, à maintenir une conduite intègre dans mon rapport au savoir, mes méthodes et mes résultats.

Entanglement distillation

Bennett *et al*, PRL, (1993)

Horodecki<sup>3</sup>, PRL (1998)

Dür, PRL (1998)

A bipartite state  $\rho$  is distillable, iff - by means  
of LOCC - we can create  $|\Psi^{(\pm)}\rangle$  out of  $n$   
identical copies of  $\rho$ .

# What is entanglement?

NPT implies entanglement

Peres, *PRL* (1996)

Some states are entangled but with PPT (*bound* entanglement)

Horodecki<sup>3</sup>, *Phys. Lett. A* (1996)

Any distillable state must be NPT.

Horodecki<sup>3</sup>, *PRL* (1998)

However, it is equivalent for two-modes Gaussian states (also 1xN)

Duan *et al*, *PRL* (2001), Werner and Wolf, *PRL* (2001)

What about Bell's inequalities?

Some states violate a Bell inequalities but are not distillable (*bounded*).  
Dür, *PRL* (2001)

"Violation of a Bell inequality implies *bipartite* distillability".

Acin, *PRL* (2001)

Any bipartite entangled state  $\sigma$  exhibits a hidden nonlocality which can be activated ( $\exists \rho$  entangled that does not violate CHSH inequality but  $\rho \otimes \sigma$  violates it)

Acin, *PRL* (2001)

If a bounded NPT state  $\sigma$  exists, then it also exists  $\rho$  PPT such that  $\rho \otimes \sigma$  is distillable (*superactivation*).

Shor, Smolin & Terhal, *PRL* (2001)

Horodecki<sup>4</sup>, *RMP* (2009)

V. Gondret – PhD defense

The state is characterized by  $n_1, n_2, \langle \hat{a}_1 \hat{a}_2 \rangle$  &  $\langle \hat{a}_1^\dagger \hat{a}_2 \rangle$

*Lemma 1:* Measurement of  $n_1, n_2, g_{12}^{(2)}$  &  $g_{12}^{(4)}$  yields a symmetric system for  $|\langle \hat{a}_1 \hat{a}_2 \rangle|$  &  $|\langle \hat{a}_1^\dagger \hat{a}_2 \rangle|$

- $g_{12}^{(2)}$  involves their quadratic sum,
- $g_{12}^{(4)}$  also involves their product.

We find two solutions  $\beta_\pm$

$$\beta_\pm^2 = n_1 n_2 \left( g_{12}^{(2)} - 1 \right) \frac{1 \pm \sqrt{1 - \theta}}{2}$$

where

$$\theta = \frac{g_{12}^{(4)} + 12 - 16g_{12}^{(2)} - 4 \left( g_{12}^{(2)} - 1 \right)^2}{\left( g_{12}^{(2)} - 1 \right)^2}$$

*Hypothesis*

- ✓ Gaussian state
- ✓ Zero mean
- ✓  $\langle \hat{a}_1^2 \rangle = \langle \hat{a}_2^2 \rangle = 0$

$\theta \in [0,1]$  so that  $\beta_\pm^2 \geq 0$  as a supplementary check for the consistency of the hypothesis.

We have two possible solutions

- “State”  $\mu$ :  $|\langle \hat{a}_1 \hat{a}_2 \rangle| = \beta_+$  &  $|\langle \hat{a}_1^\dagger \hat{a}_2 \rangle| = \beta_-$ ,
- “State”  $\gamma$ :  $|\langle \hat{a}_1 \hat{a}_2 \rangle| = \beta_-$  &  $|\langle \hat{a}_1^\dagger \hat{a}_2 \rangle| = \beta_+$ .

$$g_{12}^{(4)} = \langle \hat{a}_1^{\dagger 2} \hat{a}_2^{\dagger 2} \hat{a}_1^2 \hat{a}_2^2 \rangle / n_1^2 n_2^2$$

We have two possible solutions

- “State”  $\mu$ :  $|\langle \hat{a}_1 \hat{a}_2 \rangle| = \beta_+$  &  $|\langle \hat{a}_1^\dagger \hat{a}_2 \rangle| = \beta_-$ ,
- “State”  $\gamma$ :  $|\langle \hat{a}_1 \hat{a}_2 \rangle| = \beta_-$  &  $|\langle \hat{a}_1^\dagger \hat{a}_2 \rangle| = \beta_+$ .

check they  
can exist!

*Lemma 2:*

The *bona fide* condition does not depend on the phase of  $\langle \hat{a}_1 \hat{a}_2 \rangle$  and  $\langle \hat{a}_1^\dagger \hat{a}_2 \rangle$ .

The (smallest) eigenvalue is given by

$$v_\mu = f(n_1, n_2, \beta_+, \beta_-) \quad \& \quad v_\gamma = f(n_1, n_2, \beta_-, \beta_+)$$

We have 3 possibilities

- $v_\gamma \leq v_\mu < 1$ : unphysical states (wrong hypothesis)
- $v_\gamma < 1 \leq v_\mu$ : only one solution (we found it),
- $1 \leq v_\gamma \leq v_\mu$ : two solutions and we cannot distinguish the states

$$f(n_1, n_2, x, y) = \frac{\Delta - \sqrt{\Delta^2 - \det \sigma}}{2}$$

where

$$\det \sigma = 16(x^2 - y^2)^2 + (1 + 2n_1)^2(1 + 2n_2)^2 - 9(x^2 + y^2)(1 + 2n_1)(1 + 2n_2)$$

and

$$\Delta = (2n_1 + 1)^2 + (2n_2 + 1)^2 - 8(x^2 - y^2)$$

*Hypothesis*

- ✓ Gaussian state
- ✓ Zero mean
- ✓  $\langle \hat{a}_1^2 \rangle = \langle \hat{a}_2^2 \rangle = 0$

*Lemma 3:*

‘States’  $\mu$  and  $\gamma$  are partial transpose of each other.

The state is entangled

The state is separable

## Entanglement criterion

- Measure  $n_1, n_2, g_{12}^{(2)}$  &  $g_{12}^{(4)}$  and deduce  $\beta_{\pm}$ ,
- Compute  $v_{\gamma} = f(n_1, n_2, \beta_{-}, \beta_{+})$
- The state is entangled iff  $v_{\gamma} < 1$ , (criterion)
- Quantify entanglement  $\text{LN} = \text{Max}(-\log_2 v_{\gamma}, 0)$

Without  $g_{12}^{(4)}$ ,  $g_{12}^{(2)}$  is still a witness!

*Hypothesis*

- ✓ Gaussian state
- ✓ Zero mean
- ✓  $\langle \hat{a}_1^2 \rangle = \langle \hat{a}_2^2 \rangle = 0$

Fig: Entanglement in the  $(g_{12}^{(2)}, \theta)$  plane for three populations.

## Entanglement criterion

- Measure  $n_1, n_2, g_{12}^{(2)}$  &  $g_{12}^{(4)}$  and deduce  $\beta_{\pm}$ ,
- Compute  $\nu_{\gamma} = f(n_1, n_2, \beta_{-}, \beta_{+})$
- The state is entangled iff  $\nu_{\gamma} < 1$ , (*criterion*)
- Quantify entanglement  $LN = \text{Max}(-\log_2 \nu_{\gamma}, 0)$

Fig: Trying to use the  $g4/g2$  criterion with experimental data

## The debate

Consider  $\hat{a}_\uparrow^\dagger \hat{a}_\downarrow^\dagger |vac\rangle = |1,1\rangle$  in 2<sup>nd</sup> quantization.

In the 1<sup>st</sup> quantized picture, labelling particles by A and B, we have

$$\frac{|\uparrow\rangle_A |\downarrow\rangle_B + |\downarrow\rangle_A |\uparrow\rangle_B}{\sqrt{2}}$$

which is entangled?

For some, this ‘entanglement’ is unphysical and the labels A and B are meaningless.

No consensus on the nature of this correlation due to exchange symmetry, sometime referred to as *particle entanglement*.

Nevertheless, particle entanglement is a useful and consistence resource”

Morris *et al.* PRX **10** (2020)

“Identical particle entanglement can be transferred, with unit probability, onto independent modes using elementary operations. Thus, symmetrization entanglement is a fundamental, ubiquitous, and readily extractable resource for standard quantum information tasks.”

Killoran, Cramer and Plenio, PRL **112** (2014)

New definitions of entanglement have been proposed but only Werner’s definition based on the *mode entanglement* is satisfying

Benatti *et al.* Phys. Rep. (2020).

Violation of the Cauchy-Schwarz inequality is a particle entanglement witness

Wasak *et al.* PRA. (2014).

(I strongly recommend to read the introduction of Morris *et al* and Killoran *et al.*)

Fig: Entanglement witness based on the value of  $g_{12}^{(2)}$ .

- The  $g_{12}^{(2)}$  entanglement witness depends on the populations,
- The value of  $g_{12}^{(4)}$  is needed to determine the entanglement in the '??'.
- Taking into account the quantum efficiency of the detector can 'help' to witness entanglement,

## Hypothesis

- ✓ Gaussian state
- ✓ Zero mean
- ✓  $\langle \hat{a}_1^2 \rangle = \langle \hat{a}_2^2 \rangle = 0$

If  $\langle \hat{a}_j^2 \rangle \neq 0$ , the phases matter in the state's non-separability.
