Pairings in isogeny based cryptography

- [CSV2020]: Tate pairing to attack isogeny-DDH;
Genus theory describes the characters $\chi : \text{Cl}(O) \rightarrow \pm 1$, and the Tate pairing can be used to compute $\chi(\mathfrak{a})$;
- [CHVW2022]: Weil pairing to compute $\chi(\mathfrak{a})$;
- [CHMMvBV2023]: Generalised Tate pairing to attack the class group action;
⇒ Applies when Δ_O has a large enough smooth factor

- This talk: CSIDH
- Infinitesimal pairings
- Work in progress (Euphemism for “I don’t know how to compute anything”)
- More questions than answers...

The Weil-Cartier pairing

- If $\gamma \in \text{End}(E)$ of norm d , **non degenerate** pairing

$$e_\gamma : E[\gamma] \times E[\hat{\gamma}] \rightarrow \mu_d.$$

- Primitively **oriented elliptic curve**: \mathcal{O} quadratic imaginary order of discriminant $\Delta = \Delta_{\mathcal{O}} < 0$;
 - Special case $\gamma = \alpha := \sqrt{\Delta}$;
 - $E[\alpha]$ is **cyclic** (the orientation is primitive);
 - $E[\hat{\alpha}] = E[\alpha]$ ($\hat{\alpha} = \bar{\alpha} = -\alpha$);
- $\Rightarrow e_\alpha : E[\alpha] \times E[\alpha] \rightarrow \mu_\Delta$ is a **non degenerate self pairing** of order Δ .
- $e_\alpha(P, Q) = e_\Delta(P, Q')$ for $\alpha(Q') = Q$

Application 1: reconstructing an isogeny [CHMMvBV2023]

- $\phi : E_A \rightarrow E_B$ unknown oriented isogeny of **known degree n** ;
 - $\phi(E_A[\gamma]) = E_B[\gamma]$
 - $\gamma = [\ell] : e_\ell$ gives constraints on $\phi \mid E_A[\ell]$;
 - γ cyclic: via the Weil pairing e_γ , recover the action of ϕ on $E_A[\hat{\gamma}]$ from the action on $E_A[\gamma]$.
-
- Special case: $\gamma = \alpha$;
 - $e_\alpha(\phi(P), \phi(P)) = e_\alpha(P, P)^n$;
 - If $Q \in E_B[\alpha]$ such that $e_\alpha(Q, Q) = e_\alpha(P, P)$, then $\phi(P) = c \cdot Q$ with $c^2 = n$ modulo Δ ;
- ⇒ Recover $\phi(P)$ up to a “sign” μ ($\mu^2 = 1$ modulo Δ)
- If $\Delta > n$ this is enough to recover ϕ (Kani+Zarhin+Banff/Bristol workshop)

Application 2: genus theory

- If $\ell \mid \Delta$ odd prime, character χ_ℓ on $\text{Cl}(O)$:

$$\chi_\ell([\mathfrak{a}]) = \left(\frac{N(\mathfrak{a})}{\ell} \right) \in \{\pm 1\}$$

- Special formulas for $\ell = 2$;
- There is exactly one non trivial relation between the characters.
- $\phi_{\mathfrak{a}} : E_A \rightarrow E_B = \mathfrak{a} \cdot E_A$
- $U_A = \{e_\alpha(P, P)^{\Delta/\ell} \mid P \in E_A[\alpha]\} = \{\zeta_A^{i^2} \mid i \in \{1, \dots, \Delta\}\},$
 $U_B = \{e_\alpha(Q, Q)^{\Delta/\ell} \mid Q \in E_B[\alpha]\} = \{\zeta_B^{i^2} \mid i \in \{1, \dots, \Delta\}\} = \{\zeta_A^{N(\mathfrak{a})i^2} \mid i \in \{1, \dots, \Delta\}\};$
- $\chi_\ell([\mathfrak{a}]) = 1 \Leftrightarrow U_A = U_B,$
 $\chi_\ell([\mathfrak{a}]) = -1 \Leftrightarrow U_A \cap U_B = \{1\}.$
- $[\mathfrak{a}][\mathfrak{b}] = [\mathfrak{b}'][\mathfrak{a}'],$ DDH: check if $[\mathfrak{a}] = [\mathfrak{a}']$ ($\Leftrightarrow [\mathfrak{b}] = [\mathfrak{b}']$)?
- Genus check: $\chi_\ell([\mathfrak{a}]) = \chi_\ell([\mathfrak{a}'])$ for all $\ell \mid \Delta$?

Generalised Tate pairings

- If $m \mid \Delta$, e_α induces a non degenerate pairing (the generalised Tate pairing)

$$E[\alpha, m] \times E[\alpha]/mE[\alpha] \rightarrow \mu_m$$

- If $P = \frac{\Delta}{m}P' \in E[\alpha, m]$ and $Q = mQ' \in E[\alpha]/mE[\alpha]$,

$$e_\alpha(P, Q) = e_m(P, \hat{\alpha}(Q')) = e_\alpha(P', Q) \frac{\Delta}{m} = e_\Delta(P', \hat{\alpha}(Q')) \frac{\Delta}{m}$$

- $P \in E[\alpha] \mapsto e_\alpha(\frac{\Delta}{m}P, P)$ induces a self pairing of order m on $E[\alpha, m]$;
- Allows to restrict to the smooth part of Δ .

- Usual Tate pairing: $\alpha = \pi - 1$;
- Generalised Tate-Cartier pairing: if $\psi_2 \circ \sigma_1 = \sigma_2 \circ \psi_1$,
 $e_{\sigma_1} : A_1[\sigma_1] \times A_2[\hat{\sigma}_1] \rightarrow \mathbb{G}_m$ induces

$$A_1[\sigma_1, \psi_1] \times \hat{A}_2[\hat{\sigma}_1]/\hat{\psi}_2(\hat{B}_2[\hat{\sigma}_2]) \rightarrow \mathbb{G}_m$$

and $e_{\sigma_1}(P_1, Q_2) = e_{\psi_1}(P_1, \hat{\sigma}_2 Q')$ where $\hat{\psi}_2 Q' = Q$.

- In CSIDH/CSURF: E/\mathbb{F}_p supersingular elliptic curve
 - $\Delta = -4p$ or $\Delta = -p$;
 - Needs $\ell = p$ to get meaningful information
 - Infinitesimal Weil pairing: $e_p : E[p] \times E[p] \rightarrow \mu_p$
 - $\alpha = \pi$ is the Frobenius
 - Infinitesimal self pairing: e_π on $E[\pi]$ with values in μ_p
 - $e_\pi(P, Q) = e_p(P, Q')$ where $\pi(Q') = Q$.
-
- E/k supersingular curve, k perfect of characteristic p
 - $E[\pi] = \{(X : Y : Z) \in E \mid (X^p : Y^p : Z^p) = (0 : 1 : 0)\} \simeq \alpha_p = \text{Spec } k[X]/X^p$
 - $E[p] = \{(X : Y : Z) \in E \mid (X^{p^2} : Y^{p^2} : Z^{p^2}) = (0 : 1 : 0)\} \simeq I_{1,1}$
the unique autodual non split extension of α_p by itself
 - $\mu_p = \text{Spec } k[X]/(X^p - 1)$

Dieudonné theory

- Dieudonné ring: $A = W(k)\{F, V\}$ with $VF = FV = p, F\lambda = \lambda^\sigma F, \lambda V = V\lambda^\sigma$
(σ Frobenius on $W(k)$)
- Anti-equivalence of category $G \mapsto \mathbb{D}(G)$ from finite (flat) commutative group schemes of p -primary degree to left A -modules of finite $W(k)$ -length
- F corresponds to the Frobenius on G and V to the Verschiebung
- Functorial in k
- If $p \cdot G = 0$ then $\mathbb{D}(G)$ is a $k\{F, V\}$ -module;
- Extends to p -divisible groups: anti-equivalence between p -divisible groups G of height n and free left A -modules of rank n
- Composing with duality we get a covariant theory but which permutes the role of F and V

Examples

- If G/k of order p , $\mathbb{D}(G)$ is a k -vector space of dimension 1 with some action by F and V
- $\mathbb{D}(\mathbb{Z}/p\mathbb{Z}): F = 1, V = 0$
- $\mathbb{D}(\mu_p): F = 0, V = 1$
- $\mathbb{D}(\alpha_p): F = 0, V = 0$

- If E/k is an elliptic curve, $E(p)$ is a p -divisible group of height 2, $\mathbb{D}(E(p))$ is a free $W(k)$ -module of rank 2
- If E/k is ordinary, $E(p) = E_{\text{etale}}(p) \times E_{\text{mult}}(p)$,

$$\mathbb{D}(E(p)) = \mathbb{D}(E_{\text{etale}}(p)) \oplus \mathbb{D}(E_{\text{mult}}(p))$$

$$F = \begin{pmatrix} \lambda & 0 \\ 0 & \mu \end{pmatrix}, V = \begin{pmatrix} \mu & 0 \\ 0 & \lambda \end{pmatrix}$$

λ, μ the two eigenvalues, λ invertible modulo p

- If E/k is supersingular,

$$F = \begin{pmatrix} 0 & 1 \\ p & 0 \end{pmatrix}$$

and $V = -F$ on $\mathbb{D}(E[p])$.

Duality [Oda 1969], [Berthelot, Breen, Messing 1979]

- **Duality** behaves as expected for the p -divisible group $A(p)$ of an abelian variety A/k : we have a canonical (functorial) isomorphism

$$A^\vee(p) \simeq A(p)^\vee$$

- Duality behaves as expected for Dieudonné theory:

$$\mathbb{D}(G^\vee) \simeq \mathbb{D}(G)^\vee$$

⇒ **Pairing**: $\mathbb{D}(A(p)) \times \mathbb{D}(A^\vee(p)) \rightarrow \mathbb{D}(\mathbb{G}_m)$

- Weil pairing: $e_p : A[p] \times A^\vee[p] \rightarrow \mu_p$
- If A is principally polarised:

$$e_p : \mathbb{D}(A[p]) \times \mathbb{D}(A[p]) \rightarrow \mathbb{D}(\mu_p)$$

Infinitesimal self pairing for supersingular elliptic curves

- Frobenius filtration: $0 \rightarrow E[\hat{\pi}] \rightarrow E[p] \rightarrow E[\pi] \rightarrow 0$ induces

$$0 \rightarrow \mathbb{D}(E[\pi]) \simeq \mathbb{D}(\alpha_p) \rightarrow \mathbb{D}(E[p]) \rightarrow \mathbb{D}(E[\hat{\pi}]) \simeq \mathbb{D}(\alpha_p) \rightarrow 0$$

- On a compatible symplectic basis (e_1, e_2) , $e_1 \in \mathbb{D}(E[\pi])$:

$$F|_{\mathbb{D}(E[p])} = \begin{pmatrix} 0 & c \\ 0 & 0 \end{pmatrix}$$

with $e_p(e_1, e_2) = 1 \in \mathbb{D}(\mu_p)$

- Since $F(e_2/c) = e_1$,

$$e_\pi(e_1, e_1) = e_p(e_1, e_2/c) = 1/c$$

Infinitesimal pairings for CSIDH

- 1 Find a symplectic basis e_1, e_2 of $\mathbb{D}(E[p])$
 - 2 Compute the action of F on this basis
 - 3 Recover e_π
- ⇒ Recover $\chi_p(\mathfrak{a})$ given only the domain and codomain of $\phi_{\mathfrak{a}}$
- ⇒ If $\phi_{\mathfrak{a}} : E_A \rightarrow E_B$ unknown isogeny of known degree n , embed $\phi_{\mathfrak{a}}$ into a purely inseparable isogeny in higher dimension
- ???¹
 - Profit!

¹No reason to believe that an inseparable isogeny can be computed in time faster than $O(p^C)$; the Frobenius seems to be a special case

De Rham cohomology

- [Oda 1969]: canonical isomorphisms

$$\mathbb{D}(A[p]) \simeq H_{DR}^1(A), \mathbb{D}(A[\pi]) \simeq H^0(A, \Omega_{A/k}^1), \mathbb{D}(A[\hat{\pi}]) \simeq H^1(A, \mathcal{O}_A)$$

- De Rham cohomology: hypercohomology of the De Rham complex
- The Frobenius filtration

$$0 \rightarrow A[\hat{\pi}] \rightarrow A[p] \rightarrow A[\pi] \rightarrow 0$$

corresponds to the Hodge filtration

$$0 \rightarrow H^0(A, \Omega_{A/k}^0) \rightarrow H_{DR}^1(A) \rightarrow H^1(A, \mathcal{O}_A) \rightarrow 0$$

$\Rightarrow e_p$ is a pairing on $H_{DR}^1(A)$

- If $A = \text{Jac}(C)$, $H_{DR}^1(A) = H_{DR}^1(C)$, $H^1(A, \mathcal{O}_A) = H^1(C, \mathcal{O}_C) = H^0(C, K_C)$.
- Cup product: $H_{DR}^1(C) \times H_{DR}^1(C) \rightarrow H_{DR}^2(C) \simeq^{\text{Trace}} k$
- [Coleman]: e_p is the cup product pairing

De Rham cohomology of an elliptic curve

- $H_{DR}^1(E) \simeq H_{DR}^1(E \setminus 0_E) \simeq H^0(\Omega(2O_E)) = \langle dx/y, xdx/y \rangle$ ([Katz 1972] via log differentials)
= Differentials with a pole of order ≤ 2 at infinity
- $e_p(dx/y, xdx/y) = 1$;
- For E/\mathbb{F}_p **supersingular**: π induces from e_p a non degenerate pairing e_π on $H^0(E, \Omega_{E/k}) = \langle dx/y \rangle$;
- If $F(xdx/y) = cdx/y$,

$$e_\pi(dx/y, dx/y) = 1/c.$$

- To compute e_π , we just need to know the action of F on xdx/y
- This c depends on the curve equation $y^2 = x^3 + ax + b$;
- The change of variable $(x, y) \mapsto (x', y') = (u^2x, u^3y)$ gives $dx'/y' = 1/u \cdot dx/y$,
 $x'dx'/y' = u \cdot xdx/y$, so $c' = u^2 \cdot c$, and $e_\pi(dx'/y', dx'/y') = \frac{1}{u^2c} = \frac{1}{u^2}e_\pi(dx/y, dx/y)$.
- Kedlaya's algorithm: $O(p)$, Harvey: $O(\sqrt{p})$
(their algorithm actually computes the action of F on the Monsky-Vashnitzer cohomology which reduces modulo p to the De Rham cohomology)

De Rham cohomology of an elliptic curve: the ordinary case

- E/\mathbb{F}_q ordinary
- $A[p] = A[\pi] \oplus A[\hat{\pi}]$, $A[\hat{\pi}]$ étale and $A[\pi]$ multiplicative
- The Hodge filtration splits
- $H_{DR}^1(E) = H^0(E, \Omega_E^1) \oplus H^1(E, \mathcal{O}_E) = \langle dx/y, xdx/y \rangle$
- $\langle dx/y \rangle \simeq \mathbb{D}(E[\pi]) \simeq H^0(E, \Omega_E^1)$
- $\langle xdx/y \rangle \simeq \mathbb{D}(E[\hat{\pi}]) \simeq H^1(E, \mathcal{O}_E)$

Applications of the infinitesimal self pairing

- $\phi_\alpha : E_A \rightarrow E_B$ unknown CSIDH isogeny of known degree n
- Compute e_π on E_A and E_B
- Recover the action on differentials: $\phi_\alpha^* dx_B/y_B = \lambda dx_A/y_A$ (up to a sign)
- Solve a differential equation to recover the action of ϕ_α on the formal group up to precision $N < p$ [BMSS2008]

Deformations for CSIDH

- The action on differentials is only defined up to a sign
- Kodaira-Spencer: $H^0(E, \text{Sym}^2 \Omega_{E/k}^1) \simeq \Omega_{A_1, E}^1$
- The square of a differential determines a deformation to $k[\epsilon]/(\epsilon^2)$;
- Concretely: $j'/j = -E_6/E_4$ is a modular form of weight two and for a deformation $\tilde{E}/k[\epsilon]$,
 $j(\tilde{E}) = j(E) + j'(E)\epsilon$
- Using $e_{\pi'}$, given a deformation \tilde{E}_A of E_A to $k[\epsilon]/\epsilon^2$, we can compute the codomain \tilde{E}_B knowing only $\deg \phi_{\alpha}$;
- The CSIDH action carries additional information on the deformations!

More on deformations

- $\mathbb{D}(A(p)) = H_{crys}^1(A, W(k)) =$ hypercohomology of the De Rham-Witt complex
[Deligne-Illusie] $= H_{DR}^1(\tilde{A}/W(k))$ for any lift $\tilde{A}/W(k)$ of A/k
(this is a crystal for the crystalline topology)
- Serre-Tate: deforming $A/k =$ deforming $A(p)/k$
- Grothendieck-Messing: deforming a p -divisible group $G/k =$ deforming $\mathbb{D}(G)/k =$ deforming/lifting its Hodge filtration
- If \tilde{A}/R is a lift of A/k , the Hodge filtration on $\mathbb{D}(A(p))/R$ is the Hodge filtration on \tilde{A}
(it does lift the Hodge filtration of A/k).

- If E/\mathbb{F}_p supersingular, it lifts canonically to \tilde{E}/\mathbb{Z}_p , and an oriented CSIDH isogeny lifts
- Since \tilde{E}/\mathbb{Z}_p has supersingular reduction, the Weil pairing on $\mathbb{D}(\tilde{E}(p))/\mathbb{Z}_p$ induces a self pairing on $\mathbb{D}(\tilde{E}(p))/F\mathbb{D}(\tilde{E}(p))!$

Revisiting anomalous curves

- If E/\mathbb{F}_p is an ordinary elliptic curve, $\mathbb{D}(\hat{E}[\hat{\pi}]) \simeq H^0(E, \Omega_{E/k}^1)$ is explicitly given by $D_P \in \hat{E}[\hat{\pi}] \mapsto df_P/f_P$ where f_P is any function in $k(E)$ with divisor pD_P .
- The map $P \in E[p]_{\text{etale}} = E[\hat{\pi}] \mapsto (P) - (0_E) \in \hat{E}[\hat{\pi}] \mapsto df_P/f_P \in H^0(E, \Omega_{E/k}^1)$ efficiently transfers the DLP to a (trivial) DLP on differentials (Semaev).
- Smart: uses the p -adic elliptic logarithm on a non canonical lift to $\mathbb{Z}_p/p^2\mathbb{Z}_p$ instead.
- Canonical lift: the unique lift whose associated filtration is stable under Frobenius; p -adic elliptic logarithm: isomorphism of the formal Lie group of the elliptic curve with \hat{G}_a .
- Belding: uses the Weil pairing to a (non trivial) deformation to $\mathbb{F}_p[\epsilon]$.
- Voloch: uses p -descent.
- **In summary:** The Dieudonné functor, which replaces the algebraic group structure $E[p]$ with differential linear data $\mathbb{D}(E[p]) \simeq H_{DR}^1(E)$ or $\mathbb{D}(E(p)) \simeq H_{crys}^1(E, \mathbb{Z}_p)$, underlies these various anomalous DLP attacks.
- Can we find an “anomalous” attack on CSIDH?
