4 Applications to exploring isogeny graphs

5 Applications to isogeny based cryptography

Ideals and isogenies: the oriented case

- $E_0/k, k = \mathbb{F}_{q^r}$ elliptic curve with a primitive orientation by a quadratic imaginary order $R = \mathbb{Z}[\sqrt{-\Delta}] \hookrightarrow \text{End}_k(E_0)$
- **Oriented isogeny:** $\phi : E_1 \rightarrow E_2$ that commutes with the orientations
- **Oriented kernel:** K stable by R
Unique R -orientation compatible on E/K with the quotient isogeny $E \rightarrow E/K$, and the isogeny is horizontal or ascending

Example: Frobenius orientation

- E_0/k with non trivial π_k -action: ordinary curves, supersingular curves over \mathbb{F}_p
- π_k -oriented isogenies = rational isogenies.

Kernels, isogenies, and ideals

- $I \mapsto \phi_I : E_0 \rightarrow E_I$ oriented isogeny with kernel $E_0[I] = \{P \in E_0(\bar{k}), \alpha(P) = 0, \forall \alpha \in I\}$
- $K \mapsto \mathfrak{I}(K) := \{\alpha \in R \mid \alpha(K) = 0\}$
- $I \rightarrow E_0[I] \Leftrightarrow K \mapsto \mathfrak{I}(K)$: bijections¹ between R -stable kernels and integral ideals I of R
- **Ideals** \Leftrightarrow **oriented isogenies**
- $I \sim J \Leftrightarrow E_I \simeq E_J$

¹At least in the separable case: $E_0[\pi_p]$ is not represented by an ideal if p inert in R

Class group actions

- $E_I := E_0/E_0[I]$ primitively oriented by $O(I) := \{\alpha \in R \otimes_{\mathbb{Z}} \mathbb{Q} \mid \alpha I \subset I\}$
- I is invertible $\Leftrightarrow O(I) = R \Leftrightarrow$ the isogeny is horizontal
- $\text{Pic}(R) := \{[I], I \text{ invertible ideal}\}$

- Invertible ideals I of $R \Leftrightarrow$ oriented horizontal isogenies $\phi_I : E \rightarrow E_I$
[Colò-Kohel 2020, Onuki 2020]
- $\widetilde{\phi}_I = \phi_{\bar{I}} : E_I \rightarrow E$
- Special case: p inert in R (can only happen for an orientation on a supersingular curve $E/\mathbb{F}_{p,2}$)
- $\pi_p : E \rightarrow E^\sigma$ is not represented by an ideal
- An oriented isogeny $\phi : E \rightarrow E'$ comes from an ideal iff the representations $\rho_R(E)$ and $\rho_R(E')$ are equivalent, $\rho_R(E)$ representation of R on the k -vector space $T_0(E)$

Group action:

- $\text{Pic}(R) \curvearrowright \{E \text{ primitively } R\text{-oriented}\}$
- $[I] \cdot E \mapsto E_I$
- Free and transitive action (if p ramified or split; two orbits if p inert in R)

- $E[\mathfrak{m}](\bar{k}) \simeq R/\mathfrak{m}R$ as R -modules [Lenstra 1996] ($p \nmid \mathfrak{m} = 1$)
- Generalised class group action (ray class groups modulo \mathfrak{m}) to incorporate \mathfrak{m} -level structure [ACELV 2024]

Applications of class group actions

- Let $\{E_1, \dots, E_N\}$ be the orbit of E_0 under $\text{Pic}(R)$. Then $H(X) = \prod (X - j(E_i))$ is the reduction modulo p of the Hilbert class polynomial H_R .
- Reduction modulo p of CM class polynomials can also be understood in terms of actions by the Shimura class group
- The CRS/ CSIDH key exchange:

$$\begin{array}{ccc} E_0 & \longrightarrow & E_{I_1} = I_1 \cdot E_0 \\ \downarrow & & \downarrow \\ E_{I_2} = I_2 \cdot E_0 & \longrightarrow & E_{I_1 \otimes_R I_2} \simeq I_1 I_2 \cdot E_0 \end{array}$$

 As a commutative group action, susceptible to Kuperberg's subexponential quantum algorithm

Ideals and isogenies: the supersingular case

- **Deuring correspondance**
- Maximal orders O in $B_{p,\infty} =$ supersingular curves E/\mathbb{F}_{p^2} (up to quadratic twists and Galois conjugates)
- $I \mapsto E_0[I], K \mapsto \mathfrak{J}(K)$: bijection between kernels and left O_0 -ideals ($O_0 = \text{End}(E_0)$)
- **Ideals \Leftrightarrow Isogenies**
- $\text{End}(E_I) = O_R(I)$ the right order of I ; $\deg \phi_I = N(I) := \text{nrd}(I)$

Ideal to isogeny: $I \Leftrightarrow E_0 \rightarrow E_I := E_0/E[I]$

- Not a group action!
- SIDH relied on pushforwards, these depend on the paths, so need extra informations:

$$\begin{array}{ccc} E_0 & \longrightarrow & E_1 \\ \downarrow & & \downarrow \\ E_2 & \longrightarrow & E_{12} \end{array}$$

3 The module action on elliptic curves

4 Applications to exploring isogeny graphs

5 Applications to isogeny based cryptography

The power object in an abelian category

- $A \in \mathcal{A}$ an abelian category, $R \subset \text{End}_{\mathcal{A}}(A)$
- If $X \in \mathcal{A}$, $\text{Hom}_{\mathcal{A}}(X, A)$ has a natural R -module structure
- If M f.p. R -module, the **power object** $\mathcal{HOM}_R(M, A)$ exists in \mathcal{A} :

$$\text{Hom}_{\mathcal{A}}(X, \mathcal{HOM}_R(M, A)) = \text{Hom}_R(M, \text{Hom}_{\mathcal{A}}(X, A)) \quad \forall X \in \mathcal{A}$$

- If R is commutative, we have an abelian category \mathcal{A}_R of R -oriented objects, and $\mathcal{HOM}_R(M, A)$ is naturally R -oriented, and is the power object both in \mathcal{A} and \mathcal{A}_R .
- Symmetric monoidal contravariant action:

$$M \cdot A := \mathcal{HOM}_R(M, A)$$

- $M_1 \cdot M_2 \cdot A = (M_1 \otimes_R M_2) \cdot A$
- Functorial action: morphisms and objects act on morphisms and objects
- The **copower object** $M \otimes_R A$ also exists in \mathcal{A} :

$$\text{Hom}_{\mathcal{A}}(M \otimes_R A, X) = \text{Hom}_R(M, \text{Hom}_{\mathcal{A}}(A, X)) \quad \forall X \in \mathcal{A}$$

- If R commutative, this is also the copower object in \mathcal{A}_R and we have a covariant action $M \mapsto M \otimes_R A$
- All monoidal actions are of this type (using an enrichment in a presheaf category)

Explicit constructions of the power object

- $\mathcal{HOM}_R(R^n, A) = A^n$

$$\begin{aligned} R^m &\xrightarrow{F} R^n \rightarrow M \rightarrow 0 \\ 0 &\rightarrow \mathcal{HOM}_R(M, A) \rightarrow A^n \xrightarrow{F^T} A^m \end{aligned}$$

- If M **projective module**, $R^n = M \oplus M' \Rightarrow$

$$A^n = \mathcal{HOM}_R(M, A) \oplus \mathcal{HOM}_R(M', A)$$

- Splitting of idempotents

Theorem (The action by projective modules)

If $\text{End}_R(A) = R$, then $\text{Hom}_R(M_2, M_1) = \text{Hom}_{\mathcal{A}_R}(M_1 \cdot A, M_2 \cdot A)$ for M_1, M_2 f.p. projective R -modules.

The action $M \mapsto M \cdot A$ gives an **antiequivalence of category** between f.p. projective R -modules and the **Cauchy completion** (for categories enriched in R -modules) of A in \mathcal{A}_R .

Exactness properties

- Left exact on the left and right exact on the right:

$$\begin{aligned}0 \rightarrow M_2 \hookrightarrow M_1 \twoheadrightarrow M_1/M_2 \rightarrow 0, \\ 0 \rightarrow (M_1/M_2) \cdot A \rightarrow M_1 \cdot A \rightarrow M_2 \cdot A\end{aligned}$$

$$\begin{aligned}0 \rightarrow A_1 \hookrightarrow A_2 \rightarrow A_3 \rightarrow 0, \\ 0 \rightarrow M \cdot A_1 \rightarrow M \cdot A_2 \rightarrow M \cdot A_3\end{aligned}$$

- The right exact functor $\mathcal{H}OM_R(\cdot, A)$ gives rise to derived functors $\mathcal{E}xt_R^i(\cdot, A)$
- Taking a free resolution of M , applying $\mathcal{H}OM_R(\cdot, A)$ and taking the cohomology gives the $\mathcal{E}xt_R^i$

$$\begin{aligned}0 \rightarrow M_2 \hookrightarrow M_1 \twoheadrightarrow M_1/M_2 \rightarrow 0, \\ 0 \rightarrow (M_1/M_2) \cdot A \rightarrow M_1 \cdot A \rightarrow M_2 \cdot A \rightarrow \mathcal{E}xt_R^1(M_1/M_2, A) \rightarrow \mathcal{E}xt_R^1(M_1, A) \rightarrow \dots\end{aligned}$$

The power object on abelian varieties

- \mathcal{A} abelian category of proper group schemes over the base field k
- If A/k is an abelian variety with $R \subset \text{End}(A)$, $M \cdot A$ is a proper group scheme in general
- If R domain,

$$\dim M \cdot A = \text{rank}_R M \times \dim A$$

- If M projective, $M \cdot A$ is an abelian variety
- More generally, we say that M is compatible with A if M is torsion free and $M \cdot A$ is an abelian variety

If R is a domain and $0 \rightarrow M \rightarrow R^n \rightarrow P \rightarrow 0$, $M \cdot A$ is an abelian variety iff $\text{Ext}_R^1(P, A) = 0$.

Example

- Torsion: $R/I \cdot A = A[I]$
- Rational points: $(M \cdot A)(k') \simeq \text{Hom}_R(M, A(k'))$, k' a k -algebra

We can define the Ext_R^i more formally by embedding group schemes over k in the category of fpqc sheaves over k .

From now on, we implicitly assume that M is compatible with A

Isogenies

Definition (Module isogeny)

A **module isogeny** is a monomorphism $M_2 \hookrightarrow M_1$ of torsion free modules with finite cokernel M_1/M_2

\Leftrightarrow monomorphism $M_2 \hookrightarrow M_1$ of torsion free modules of the same rank

\Leftrightarrow finite cokernel map $M_2 \rightarrow M_1$ of torsion free modules of the same rank

Proposition (Module isogeny to abelian variety isogeny)

If R domain and each M_i is compatible with A , then $M_1 \cdot A \rightarrow M_2 \cdot A$ is an **isogeny** with kernel $(M_1/M_2) \cdot A$:

$$0 \rightarrow (M_1/M_2) \cdot A \rightarrow M_1 \cdot A \rightarrow M_2 \cdot A \rightarrow 0$$

i.e., $\text{Ext}_R^1(M_1/M_2, A) = 0$

Isogeny = epimorphism (with finite kernel) \Leftrightarrow monomorphism (=inclusion) of modules (with finite cokernel)

Duality

- $(A, \lambda_A)/k$ ppav, $\bar{\cdot}$ the Rosatti involution on $\text{End}_k(A)$
- $(R, \bar{\cdot}) \subset \text{End}(A)$ domain
- Then R is a “CM order”
- Either R is totally real and $\bar{x} = x$
- Or R is a quadratic imaginary extension of a totally real order, and \bar{x} is the complex conjugation

- $(M \cdot A)^\vee \simeq M^* \cdot A^\vee$, where $M^* = \text{Hom}_R(M, R)$ and A^\vee the dual abelian variety
- $(M \cdot A)^\vee \simeq M^\vee \cdot A$, where $M^\vee = \text{Hom}_{\bar{R}}(M, R)$

- $\psi : M_2 \rightarrow M_1, \psi \cdot A : M_1 \cdot A \rightarrow M_2 \cdot A$
- $\psi^\vee : M_1^\vee \rightarrow M_2^\vee, \gamma \mapsto (v \mapsto \gamma \circ \psi(v))$
- $\psi^\vee \cdot A : M_2^\vee \cdot A^\vee \rightarrow M_1^\vee \cdot A^\vee$.
- This is the **dual** of ψ .

Hermitian modules and polarisations

- A polarisation Φ on $B = M \cdot A$ corresponds to:
 - A morphism $B \rightarrow B^\vee$
 - Which is autodual $\Phi = \Phi^\vee : B \simeq B^{\vee\vee} \rightarrow B^\vee$
 - And induced by an ample line bundle

- A polarisation Ψ on M corresponds to:
 - A morphism $M^\vee \rightarrow M$
 - Which is autodual under the double duality: $M \simeq M^{\vee\vee}, m \mapsto (\phi \mapsto \overline{\phi(m)})$
 - And is “positive”

- This is an **integral positive definite Hermitian form** H on M^\vee
We will assume R Gorenstein for simplicity to have good biduality theorems. This is the case if the real suborder of R is maximal, e.g. R quadratic imaginary.

- **Hermitian module action**: the action by a polarised module (M, H_M) on a polarised abelian variety (A, λ_A) gives a polarised abelian variety $(M \cdot A, H_M \cdot \lambda_A)$
- If λ_A is principal and H_M unimodular, $H_M \cdot \lambda_A$ is principal.

Example

- The Shimura class group is the class group of unimodular rank 1 Hermitian R -modules
- Given a CM ppav (A, λ_A) , acting by the Shimura class group gives other CM ppavs

Hermitian forms

Definition (Hermitian forms)

- *R*-sesquilinear: $H : M \times M \rightarrow R, H(\alpha x, y) = \alpha H(x, y), H(x, \bar{\alpha}y) = H(x, y)\bar{\alpha}$
- Hermitian: $H(y, x) = \overline{H(x, y)}$
- Positive definite: $H(x, x) \in \mathbb{Z}^{>0}, \forall x \neq 0 \in M$
- Unimodular: $H : M \simeq M^\vee, m \mapsto H(m, \cdot)$
 $\Leftrightarrow M^\# := \{v \in M \otimes \mathbb{Q}, H(m, v) \in R \ \forall m \in R\} = M$

Corollary (Principal polarisations, (A, λ_A) ppav)

- Unimodular Hermitian *R*-form H on $M \Rightarrow$ Principal polarisation $\lambda : M \cdot A \rightarrow (M \cdot A)^\vee$
- *N*-similitude $\Phi : (M_2, H_2) \rightarrow (M_1, H_1)$

$$\Phi^* H_1 = N H_2$$

$$\Rightarrow N\text{-isogeny } \phi : (A_1, \lambda_{A_1}) \rightarrow (A_2, \lambda_{A_2}) \quad (A_i = M_i \cdot A)$$

Proposition (Contragredient = Adjoint)

If $\phi = \psi \cdot A : (A_1, \lambda_1) \rightarrow (A_2, \lambda_2)$ for $\psi : (M_2, H_2) \rightarrow (M_1, H_1)$, then $\tilde{\phi} = \tilde{\psi} \cdot A$, where $\tilde{\psi} : M_1 \rightarrow M_2$ is the adjoint: $H_1(\psi(x), y) = H_2(x, \psi^*(y))$

A general equivalence of category

Oriented case: E_0/k primitively oriented by R quadratic imaginary

Theorem (Module antiequivalence of category)

The action $M \mapsto M \cdot E_0$ gives an *antiequivalence of category* between the category of R -oriented abelian varieties ^a A k -isogenous to E_0^g and R -oriented k -morphisms; and the category of f.p. torsion free R -modules M of rank g and R -module morphisms.

Inverse map: $A \mapsto \text{Hom}_R(A, E_0)$: *module of (oriented) morphisms from A to E_0*

^awith the technical condition $\rho_R(A) \simeq \bigoplus_{i=1}^g \rho_R(E_0)$

[Waterhouse 1969], [Kani 2011], [Jordan, Keeton, Poonen, Rains, Shepherd-Barron, Tate 2018], [Kirschmer, Narbonne, Ritzenthaler, R. 2021], [Page-R. 2023]

Alternative approaches to equivalences of category of abelian varieties (e.g. via lifting to characteristic zero): [Deligne, Howe, Centeleghe-Stix, Marseglia]...

Example

- **Frobenius orientation**: all rational isogenies at level "above" E_0 in the volcano
- **Supersingular case**: the action by f.p. left \mathfrak{D}_0 -modules also gives an antiequivalence of categories to maximal supersingular abelian varieties, $\mathfrak{D}_0 = \text{End}(E_0)$.

Warmup: ideals

- $I \hookrightarrow R$ induces $\phi_I : E_0 = R \cdot E_0 \rightarrow E_I = I \cdot E_0$
- Canonical unimodular Hermitian form on I :

$$H_I(x, y) = \frac{x\bar{y}}{N(I)}$$

- The inclusion $(I, H_I) \subset (R, H_R)$ is a $N(I)$ -similitude
- Handles ascending isogenies: I not invertible (the R -orientation needs not be primitive on E_I)

$\phi : E_{I_1} \rightarrow E_{I_2}, \quad I_1, I_2$ invertible

- Ideal point of view: $\phi \Leftrightarrow$ some integral ideal J equivalent to $I = I_2 I_1^{-1}$
- $I^{-1} = \bar{I}/N(I)$ so if $x \in I, J := \bar{I}x/N(I) \sim I; \quad N(J) = N(x)/N(I)$
- Module point of view: $\phi \Leftrightarrow \psi : (I_2, H_R/N(I_2)) \rightarrow (I_1, H_R/N(I_1))$
- If $z \in I^{-1}: \psi_z : r \mapsto zr$ is a $N := N(z)N(I_2)/N(I_1)$ -similitude
- $z = \bar{x}/N(I), N = N(x)/N(I)$
- If I integral: canonical isogeny via $z = 1 \in R \subset I^{-1}$
- Module point of view + specific isogeny $E_0 \rightarrow E =$ ideal point of view

Forgetting the orientation on supersingular elliptic curves

- E_0/\mathbb{F}_{p^2} supersingular, $R \subset \mathfrak{D}_0 := \text{End}(E_0)$ primitive orientation
- Two type of actions: by left f.p. R -modules M_R and by left f.p. \mathfrak{D}_0 -modules $M_{\mathfrak{D}}$
- If $A = M_R \cdot_R E_0$, $A = (\mathfrak{D}_0 \otimes_R M_R) \cdot_{\mathfrak{D}_0} E_0$
- Forgetting the orientation

- Conversely: $M_R = \text{Hom}_R(A, E_0)$, $M_{\mathfrak{D}} = \text{Hom}(A, E_0)$

Example (Rational isogenies from irrational endomorphisms)

In CSIDH, if we know $\mathfrak{D} = \text{End}(E)$, we can recover $I = \text{Hom}(E, E_0)$ by linear algebra, hence the module $\mathfrak{a} = \text{Hom}_{\mathbb{F}_p}(E, E_0)$ as the morphisms in I commuting with π . This simplifies an argument due to [Castricky, Panny, Vercauteren 2019].

Similitudes to isogenies

Module morphism to morphism of abelian varieties:

$$\begin{array}{ccccccc}
 R^{m_1} & \longrightarrow & R^{n_1} & \twoheadrightarrow & M_1 & \longrightarrow & 0 \\
 \uparrow \text{---} & & \uparrow \text{---} & & \uparrow & & \\
 \vdots & & \vdots & & & & \\
 R^{m_2} & \longrightarrow & R^{n_2} & \twoheadrightarrow & M_2 & \longrightarrow & 0
 \end{array}
 \quad \Leftrightarrow \quad
 \begin{array}{ccccccc}
 0 & \longrightarrow & M_1 \cdot A & \hookrightarrow & A^{n_1} & \longrightarrow & A^{m_1} \\
 & & \downarrow & & \downarrow \text{---} & & \downarrow \text{---} \\
 0 & \longrightarrow & M_2 \cdot A & \hookrightarrow & A^{n_2} & \longrightarrow & A^{m_2}
 \end{array}$$

R^n is a projective module, so we can lift module maps. The commutative diagram allows to find the kernel of $M_1 \cdot A \rightarrow M_2 \cdot A$.

- N -similitudes $\Leftrightarrow N$ -isogenies
- $(M_2, H/N) \subset (M_1, H) \Rightarrow \phi : A_1 = M_1 \cdot A \rightarrow A_2 = M_2 \cdot A$
- $M_1 = \text{Hom}(R, M_1)$, so $m_1 \in M_1$ induces $m_1 \cdot A : A_1 \rightarrow A$
We say that M_1 is a **module orientation** on $A_1 = M_1 \cdot A$
- $\text{Ker } \phi = A_1[M_2] \subset A_1[N]$

$$A_1[M_2] := \{P \in A_1(\bar{k}), (m \cdot A)(P) = 0, \forall m \in M_2\}$$

- Equivalence **practical** if N smooth, the N -torsion on A_1 is **accessible**, and the orientation of M_1 on A_1 is **effective**

Computing the module action

- We want to compute $A = (M, H) \cdot E_0$
- Find a smooth similitude $(M, H) \rightarrow (R^g, H_R^g)$
- Then convert it to an isogeny $E_0^g \rightarrow A$
- The R^g -module orientation on E_0^g is effective (as long as the R -orientation on E_0 is)

- Clapoti(s): it suffice to build two N_1, N_2 -similitudes with $N_1 \wedge N_2 = 1$ (or small)

- There are unimodular Hermitian R -modules (M, H_M) such that no N -similitude $R^g \hookrightarrow M$ exist for any N , c.f. the arithmetic obstructions in [Kirschmer, Narbonne, Ritzenthaler, R. 2021]
- Solution: look at $R^{g+1} \hookrightarrow M \times R$

- **Conductor gap**: a N -isogeny $E_0^g \rightarrow E \times A$ (with the product polarisations) inducing a non trivial isogeny $E_0 \rightarrow E$ satisfy

$$f_{E/E_0} \mid N$$

Module kernels and kernel modules

- $A_1 = M_1 \cdot A$, M_1 -oriented abelian variety
- $M_2 \subset M_1 \mapsto A[M_2] = \{P \in A_1(\bar{k}), (m \cdot A_1)(P) = 0, \forall m \in M_2\}$
- $K \subset A_2 \mapsto M(K) = \{m \in M_1, m(K) = 0\}$
- These are **Galoisian adjunctions**
- This restrict to a **bijection between module kernels and kernel modules**
- In our case ($A \sim E_0^g$), every module is a kernel module; and a kernel is a module kernel iff A_1/K is in the orbit of A by the module action.

Isogeny to similitude:

- $\phi : A_1 \rightarrow A_2$ a N -isogeny of kernel K induced by $\psi : M_2 \rightarrow M_1$
- $A_1 = M_1 \cdot A$ with **effective orientation**
- $M_2 := \{m \in M_1, m \cdot (K) = 0\}, H_2 = H_1/N$
Needs efficient DLPs in $A_1[N]$ to compute M_2
- The orientation of M_2 on A_1 descends to an **effective orientation** on A_2
(via isogeny division, at least in nice cases)

Direct sums and pushforwards

$$(A_1, \lambda_1) = (M_1, H_1) \cdot A_0 \text{ and } (A_2, \lambda_2) = (M_2, H_2) \cdot A_0$$

Product polarisations: $(A_1 \times A_2, \lambda_1 \times \lambda_2) = (M_1 \oplus M_2, H_1 \oplus H_2) \cdot A_0$

Pushforwards:

- If $\phi_1 : A_0 \rightarrow A_1$ and $\phi_2 : A_0 \rightarrow A_2$ correspond to $\psi_1 : M_1 \rightarrow M$ and $\psi_2 : M \rightarrow M_2$, their **pushforward** A_{12} corresponds to the **fiber product** $M_1 \times_M M_2$
- If $\phi_1 : A_0 \twoheadrightarrow A_1$, $\phi_2 : A_0 \twoheadrightarrow A_2$ are isogenies, $\psi_1 : M_1 \hookrightarrow M$, $\psi_2 : M_2 \hookrightarrow M$ are **monomorphisms**, and the fiber product $M_1 \times_M M_2$ is just the **intersection** $M_1 \cap M_2 \subset M$

$$\begin{array}{ccc} A_0 & \twoheadrightarrow & A_1 \\ \downarrow & & \downarrow \\ A_2 & \twoheadrightarrow & A_{12} \end{array} \quad \Leftrightarrow \quad \begin{array}{ccc} M & \longleftarrow & M_1 \\ \uparrow & & \uparrow \\ M_2 & \longleftarrow & M_1 \cap M_2 \end{array}$$

3 The module action on elliptic curves

4 Applications to exploring isogeny graphs

5 Applications to isogeny based cryptography

Finding curves with many points

- C/\mathbb{F}_q is a defect 0 curve if $\#C(\mathbb{F}_q) = 1 + q + g[2\sqrt{q}]$
- Then $\text{Jac}(C) \sim E_0^g, E_0$ of trace $-[2\sqrt{q}]$.
- $\text{Jac}(C) = M \cdot E_0$ (if E_0 at the bottom of the volcano)

Algorithm [Kirschmer, Narbonne, Ritzenthaler, R. 2021]:

- List all unimodular Hermitian modules (M, H) over $R = \text{End}_{\mathbb{F}_q}(E_0)$
 - 1 Enumerate all O_R -genus, and construct an O_R -lattice L for each genus
 - 2 Explore adjacent lattices to L until we have found all O_R -isometry classes in the genus
 - 3 Build the R -isometry classes of unimodular lattices from the O_R -unimodular lattices
- Compute all ppavs $(A, \lambda_A) = (M, H_M) \cdot E_0$
- Find which are Jacobians of defect 0 curves
- Beware of twists! In the non hyperelliptic case, a maximal Jacobian may only correspond to a minimal curve
- We use algebraic modular forms to check in which case we are

The isogeny graph of oriented isogenies in higher dimension

Assume R quadratic imaginary, $A \sim E_0^g$, so $A = M \cdot E_0$

- M torsion free of rank g : $M \simeq R^{g-1} \oplus I$ Assume R maximal for simplicity
- $A \simeq E_0^{g-1} \times E_I$ as unpolarised varieties
- # $\text{Cl}(R)$ isomorphism classes of non-polarised R -oriented abelian varieties R -isogenous to E_0^g
- Polarisation add supersingular like graph complexity if $g > 1$ ($\text{End}_R(E_0^g) = M_g(R)$)
- Universal group action: $I \cdot (M, H_M) = (IM, H_M/N(I)) \subset (M, H_M)$ (I invertible)
- $I \cdot A = A_I := A/A[I]$
- Intuition: multiplication by $[n] \Rightarrow$ multiplication by $[I]$
- Multiple orbits; linked together by oriented isogenies (which are not multiplication by $[I]$)

Example: rational supersingular abelian surfaces

- E_0/\mathbb{F}_p supersingular, $R = \text{End}_{\mathbb{F}_p}(E) = \mathbb{Z}[\sqrt{-p}]$ (or its maximal order)
- $g = 2$: graph of supersingular abelian surfaces isogeneous to E_0^2 over \mathbb{F}_p and \mathbb{F}_p -rational isogenies
- Universal group action from $\text{Cl}(R)$
- Conjecture: $\approx p^{3/2}$ nodes ($\approx \#\text{supersingular curves} \times \#\text{Cl}(R)$)
- If $\ell = \bar{\ell}$ splits in R , $A[\ell] = A[\ell] \oplus A[\bar{\ell}] \Rightarrow$ action by ℓ and $\bar{\ell}$ and $\ell + 1$ (?) other oriented ℓ -isogenies.

Weil's restriction of supersingular elliptic curves

E_0/\mathbb{F}_p supersingular, $R = \text{End}_{\mathbb{F}_p}(E) = \mathbb{Z}[\sqrt{-p}]$

- If E/\mathbb{F}_{p^2} , its **Weil restriction** $W_{\mathbb{F}_{p^2}/\mathbb{F}_p} E$ is a p.p. abelian surface over \mathbb{F}_p (which is neither a Jacobian nor a product of curves over \mathbb{F}_p).
- The Weil restriction of an N -isogeny $\phi/\mathbb{F}_{p^2} : E_1 \rightarrow E_2$, is an \mathbb{F}_p -rational isogeny between rational the abelian surfaces $A_1 \rightarrow A_2$, $A_i = W_{\mathbb{F}_{p^2}/\mathbb{F}_p} E_i$

⇒ If E is maximal, $W_{\mathbb{F}_{p^2}/\mathbb{F}_p}(E)$ is isogeneous to E_0^2

- $\text{Hom}_{\mathbb{F}_p}(W_{\mathbb{F}_{p^2}/\mathbb{F}_p} E_1, W_{\mathbb{F}_{p^2}/\mathbb{F}_p} E_2) = \text{Hom}_{\mathbb{F}_{p^2}}(W_{\mathbb{F}_{p^2}/\mathbb{F}_p} E_1 \otimes_{\mathbb{F}_p} \mathbb{F}_{p^2}, E_2) = \text{Hom}_{\mathbb{F}_{p^2}}(E_1 \oplus E_1^\sigma, E_2) = \text{Hom}_{\mathbb{F}_{p^2}}(E_1, E_2) \oplus \text{Hom}_{\mathbb{F}_{p^2}}(E_1, E_2)^\sigma$
- The dimension 2 supersingular graph over \mathbb{F}_p contains, via the Weil restriction, the supersingular graph of elliptic curves over \mathbb{F}_{p^2} (with E collapsed with E^σ)

⇒ Convenient way to obtain \mathbb{F}_p -rational isogenies in dimension 2

⇒ Module-Inversion in dimension 2 at least as **hard** as the supersingular isogeny path problem.

- Weil restriction from the module point of view: If $\phi/\mathbb{F}_{p^2} : E_1 \rightarrow E_2$ is represented by $\psi/O_0 : I_2 \rightarrow I_1$, we can find directly the module representation $\Psi/R : M_2 \rightarrow M_1$ of $W_{\mathbb{F}_{p^2}/\mathbb{F}_p} \phi$

Symmetric monoidal actions

Definition (The module monoidal contravariant action)

- If M is a projective module, the action by M is $M \cdot A = \mathcal{H}OM_R(M, A)$.
- If $\phi : A_1 \rightarrow A_2$ is a N -isogeny, $M \cdot \phi : M \otimes_R A_1 \rightarrow M \otimes_R A_2$ is a N -isogeny.
- If $\psi : M_2 \hookrightarrow M_1$ is a N -similitude, $\psi \cdot A : M_1 \cdot A \rightarrow M_2 \cdot A$ is a N -isogeny.

Example (The action by ideals)

$I \otimes_R M \simeq IM$ when I is invertible (or simply $f_I \wedge f_M = 1$), so $I \cdot A$ recovers the usual CSIDH action

Definition (Tensor product)

If $A_1 = M_1 \cdot A_0, A_2 = M_2 \cdot A_0, A_1 \otimes_{A_0} A_2 := (M_1 \otimes_R M_2) \cdot A_0$

The module action for isogeny based cryptography

Proposition (Higher dimensional CSIDH via the monoidal action)

$$\begin{array}{ccc} A_0 & \rightsquigarrow & A_1 = M_1 \cdot A_0 \\ \Downarrow & & \Downarrow \\ A_2 = M_2 \cdot A_0 & \rightsquigarrow & A_{12} = (M_1 \otimes_R M_2) \cdot A_0 \end{array}$$

If $\dim A_0 = g_0$, $\text{rank } M_1 = g_1$, $\text{rank } M_2 = g_2$, then $\dim A_{12} = g_0 g_1 g_2$.

Example (Monoidal action by rank 2 modules: $A_0 = E_0, g_1 = g_2 = 2$)

M_i projective module of rank 2 $\Leftrightarrow E_0^2 \rightarrow A_i$ a path:

$$\begin{array}{ccc} E_0^2 & \longrightarrow & A_1 \\ \downarrow & & \Downarrow \\ A_2 & \rightsquigarrow & A_1 \otimes_{E_0} A_2 \end{array}$$

Common secret: the dimension 4 abelian variety $A_1 \otimes_{E_0} A_2$

The module action for isogeny based cryptography

Proposition (Higher dimensional CSIDH via the monoidal action)

$$\begin{array}{ccc} A_0 & \rightsquigarrow & A_1 = M_1 \cdot A_0 \\ \Downarrow & & \Downarrow \\ A_2 = M_2 \cdot A_0 & \rightsquigarrow & A_{12} = (M_1 \otimes_R M_2) \cdot A_0 \end{array}$$

If $\dim A_0 = g_0$, $\text{rank } M_1 = g_1$, $\text{rank } M_2 = g_2$, then $\dim A_{12} = g_0 g_1 g_2$.

☹ Acting by rank g projective modules increase the dimension if $g > 1$

😊 Protects (hopefully!) from Kuperberg

- **Security:** Action-DDH \leq Action-CDH \leq Action-Inversion

- Action-Inversion \approx HomModule-Inversion

Indeed, if $M = \text{Hom}_R(A, E_0)$, then $A = M \cdot E_0$

Recall that, thanks to Weil's restriction, Module-Inversion on supersingular abelian surfaces over \mathbb{F}_p is at least as hard as solving the supersingular isogeny path problem over \mathbb{F}_{p^2}

- Action-CDH: **Hope** for exponential quantum security when $g > 1$

Computing the symmetric monoidal action

M_1 projective of rank g , $A_1 = M_1 \cdot E_0$

We want to compute $M_1 \cdot A_2$ for an R -oriented A_2 (with effective R -orientation)

General idea: look at how we construct $A_1 = M_1 \cdot E_0$ from E_0 , and apply the same recipe replacing E_0 by A_2 .

The smooth case:

- Suppose we can construct a smooth similitude $R^g \subset M_1$ (by duality, this is equivalent to constructing a smooth isogeny $E_0^g \rightarrow A_1$), this gives us a smooth similitude $A_2^g \rightarrow M_1 \cdot A_2$
- Via the orientation, we can transpose the kernel of $E_0^g \rightarrow A_1$ to the kernel of $A_2^g \rightarrow M_1 \cdot A_2$. The codomain gives us $M_1 \cdot A_2$
- Similar to the usual way the CSIDH action is computed

The general case:

- If instead A_1 is computed via Clapoti(s), splitting an appropriate endomorphism on $E_0^{g_1}$
- Then we can compute $M_1 \cdot A_2$ by splitting an appropriate endomorphism on $A_2^{g_1}$
- ☹ Needs to work in dimension $2g_1g_2$

Computing the symmetric monoidal action: the smooth case

$$R^g \longleftarrow M_1 \quad \Leftrightarrow \quad E_0^g \longrightarrow A_1$$

$$M_2^g \longleftarrow M_1 \otimes_R M_2 \quad \longrightarrow \quad A_2^g \twoheadrightarrow A_1 \otimes_{E_0} A_2 = M_1 \cdot A_2$$

Proposition (Computing projective module actions: the smooth case)

If $E_0^g \twoheadrightarrow A_1 \Leftrightarrow M_1 \hookrightarrow R^g$, we can compute $A_1 \otimes_{E_0} A_2$ as the quotient of $A_2^g = E_0^g \otimes_{E_0} A_2$ given by the kernel $K \subset A_2^g$ induced by $M_1 \otimes M_2 \hookrightarrow R^g \otimes M_2$: if M_1 is generated by (m_1, \dots, m_n) , and $m_i = (\alpha_{i1}, \dots, \alpha_{ig}) \in R^g$, then $K = A_2^g[m_1 \otimes M_2, \dots, m_n \otimes M_2]$ and

$$A_2^g[m_i \otimes M_2] = \text{Ker } A_2^g \xrightarrow{(\alpha_{ij})} A_2$$

Corollary (Computing the action in practice)

- If A_1 is the quotient of E_0^g by $E_0^g[m_1, \dots, m_n]$, where $E_0^g[m_i] = \text{Ker}(E_0^g \rightarrow E_0, (P_1, \dots, P_g) \mapsto \sum \alpha_{ij} P_j)$
- Then $A_1 \otimes_{E_0} A_2$ is the quotient of A_2^g by $A_2^g[m_1 \otimes M_2, \dots, m_n \otimes M_2]$, where $A_2^g[m_i \otimes M_2] = \text{Ker}(A_2^g \rightarrow A_2, (P_1, \dots, P_g) \mapsto \sum \alpha_{ij} P_j)$
- And if $E_0^g \twoheadrightarrow A_1$ is a N -isogeny, $A_2^g \twoheadrightarrow A_1 \otimes_{E_0} A_2$ is a N -isogeny

Computing the symmetric monoidal action: the smooth case

Commutative diagram:

$$\begin{array}{ccc}
 R^{\mathcal{G}1} \otimes_R R^{\mathcal{G}2} & \longleftarrow & M_1 \otimes_R R^{\mathcal{G}2} \\
 \uparrow & & \uparrow \\
 R^{\mathcal{G}1} \otimes_R M_2 & \longleftarrow & M_1 \otimes_R M_2
 \end{array}
 \quad \Leftrightarrow \quad
 \begin{array}{ccc}
 E_0^{\mathcal{G}1} \otimes_{E_0} E_0^{\mathcal{G}2} \simeq E_0^{\mathcal{G}1\mathcal{G}2} & \longrightarrow & A_1 \otimes_{E_0} E_0^{\mathcal{G}2} \simeq A_1^{\mathcal{G}2} \\
 \downarrow & & \downarrow \\
 E_0^{\mathcal{G}1} \otimes_{E_0} A_2 \simeq A_2^{\mathcal{G}1} & \longrightarrow & A_1 \otimes_{E_0} A_2
 \end{array}$$

Pairing analogy: \otimes_{E_0} = categorified bilinear map

Assume we don't know how to compute $e(P_1, P_2)$ for general P_1, P_2 , but we know $e(P_0, P_2)$. Then if $P_1 = mP_0$, we can compute $e(P_1, P_2) = e(P_0, P_2)^m$

Here we use that $E_0^{\mathcal{G}} \otimes_{E_0} A_2 \simeq A_2^{\mathcal{G}}$ and our known path $E_0^{\mathcal{G}} \rightarrow A_1$.

Monoidal actions for isogenies

- $M'_1 \hookrightarrow M_1 \hookrightarrow R^{\mathcal{G}} \Leftrightarrow A_2^{\mathcal{G}} \rightarrow M_1 \cdot A_2 \rightarrow M'_1 \cdot A_2 \Rightarrow$ recover it via the isogeny factorisation:
 $A_2^{\mathcal{G}}[M_1 \otimes_R M_2] \subset A_2^{\mathcal{G}}[M'_1 \otimes_R M_2]$
- If $A_2 \rightarrow A'_2$, then we recover $M_1 \otimes_R A_2 \rightarrow M_1 \otimes_R A'_2$ via isogeny division:

$$\begin{array}{ccc}
 A_2^{\mathcal{G}} & \longrightarrow & M_1 \cdot A_2 \\
 \downarrow & & \downarrow \\
 A_2'^{\mathcal{G}} & \longrightarrow & M_1 \cdot A_2'
 \end{array}$$

Computing the symmetric monoidal action: the general case

$$E_0^{\mathcal{G}} \longrightarrow A_1 \longrightarrow E_0^{\mathcal{G}}$$

$$A_2^{\mathcal{G}} \longrightarrow A_1 \otimes_{E_0} A_2 \longrightarrow A_2^{\mathcal{G}}$$

Proposition (Computing projective module actions: the general case)

Assume A_1 is constructed from E_1 via Clapoti(s), i.e. constructing a N_1 and N_2 -similitude $R^{\mathcal{G}} \hookrightarrow M_1$, and then splitting the induced $N_1 N_2$ -endomorphism $\gamma : E_0^{\mathcal{G}} \rightarrow E_0^{\mathcal{G}}$. So γ is given by an explicit matrix in $M_{\mathcal{G}}(R)$.

Then $\gamma \otimes_{E_0} \text{Id}_{A_2}$ is the same matrix acting as an endomorphism $A_2^{\mathcal{G}} \rightarrow A_2^{\mathcal{G}}$ via the R -orientation, and splitting this $N_1 N_2$ -endomorphism gives $A_1 \otimes_{E_0} A_2$.

$$\begin{array}{ccc}
 E_0 & \longrightarrow & E_1 \\
 \downarrow & & \downarrow \\
 E_2 & \rightsquigarrow & W_{\mathbb{F}_p^2/\mathbb{F}_p} E_1 \otimes_{E_0} W_{\mathbb{F}_p^2/\mathbb{F}_p} E_2
 \end{array}$$

- Start with our good old friend E_0/\mathbb{F}_p supersingular (with p e.g. the SQISign2d prime)
- Alice and Bob compute (smooth or not) isogenies over $\mathbb{F}_{p^2}: E_0 \rightarrow E_1, E_0 \rightarrow E_2$
- They send $j(E_1), j(E_2)$: **no torsion information!**
- **Validation:** check that E_i is supersingular

- The **common key** is the dimension 4 ppav $A_{12} := W_{\mathbb{F}_p^2/\mathbb{F}_p} E_1 \otimes_{E_0} W_{\mathbb{F}_p^2/\mathbb{F}_p} E_2$

Alice can compute it by converting her isogeny $E_0 \rightarrow E_1$ to the module map representing

$$E_0^2 = W_{\mathbb{F}_p^2/\mathbb{F}_p} E_0 \rightarrow W_{\mathbb{F}_p^2/\mathbb{F}_p} E_1 \text{ and then applying the module action to } W_{\mathbb{F}_p^2/\mathbb{F}_p} E_2.$$

The smooth case requires a dimension 4 isogeny, and the non smooth case requires splitting a dimension 4 endomorphism, so a dimension 8 isogeny...

- **Size:** $p = 2\lambda, j(E_i) = 2 \log_2(p) = 4\lambda: 64B$. **Very compact!**
- **NIKE.** PKE a la ElGamal/SiGamal

 Need good dimension 4 modular invariants to represent A_{12} (e.g. suitable symmetric polynomials in the theta constants?)

 **Security?** Action-CDH on supersingular abelian surfaces coming from the Weil restriction of elliptic curves

$$\begin{array}{ccc}
 E_0 & \longrightarrow & E_1 \\
 \downarrow & & \downarrow \\
 E_2 & \rightsquigarrow & W_{\mathbb{F}_p^2/\mathbb{F}_p} E_1 \otimes_{E_0} W_{\mathbb{F}_p^2/\mathbb{F}_p} E_2
 \end{array}$$

Example of parameters:

- $p = u2^e - 1$. Ex: $p = 5 \cdot 2^{248} - 1$.
- Alice and Bob each compute a 2^e -isogeny from E_0 over \mathbb{F}_{p^2}
- Then the common key requires computing a 2^e -isogeny in dimension 4 over \mathbb{F}_p
- Unfortunately, for the dimension 4 isogeny, the theta null point will only be defined over \mathbb{F}_{p^2} , so our known isogeny formulas will require to work over \mathbb{F}_{p^2} for the dimension 4 isogeny too
- Solution: use Scholten's construction $W'_{\mathbb{F}_2/\mathbb{F}_p}$ instead of the Weil restriction
- Start with E_0 at the bottom of the 2-volcano, $\text{End}(E_0) = R = \mathbb{Z}[\sqrt{-p}]$
- The climbing 2-isogeny is given by $E_0 \rightarrow \mathfrak{f}E_0$, \mathfrak{f} the conductor ideal in $O_R = \mathbb{Z}[(1 + \sqrt{-p})/2]$
- $W'_{\mathbb{F}_{p^2}/\mathbb{F}_p} E = \mathfrak{f}W_{\mathbb{F}_{p^2}/\mathbb{F}_p} E \Rightarrow$ explicit construction in term of modules
- Special case: If $E_0 : y^2 = x^3 + x$, $E'_0 : y^2 = x^3 - x$ is its quartic twist, and $W'_{\mathbb{F}_{p^2}/\mathbb{F}_p} E'_0 = E_0'^2$

$$\begin{array}{ccc}
 E_0 & \longrightarrow & E_1 \\
 \downarrow & & \downarrow \\
 E_2 & \rightsquigarrow & W_{\mathbb{F}_p^2/\mathbb{F}_p} E_1 \otimes_{E_0} W_{\mathbb{F}_p^2/\mathbb{F}_p} E_2
 \end{array}$$

Example of parameters:

- $p = u2^e - 1$. Ex: $p = 5 \cdot 2^{248} - 1$.
- Alice and Bob each compute a 2^e -isogeny from E_0 over \mathbb{F}_{p^2} ☹☹☹
- Then the common key requires computing a 2^e -isogeny in dimension 4 over \mathbb{F}_p
- I am beginning to have **serious doubts** about the security of action-CDH when both isogenies have the same degree 2^e
- Solution: take coprime degrees
- ☹ Unfortunately this slows down the scheme
- Either we use 2^e and 3^f -isogenies like in SIDH, but this requires to double the size of p to obtain the required torsion, so this **double the key size**. And a 3-isogeny in dimension 4 is going to be $\approx 5\times$ slower than a 2-isogeny
- Or we build our isogenies via Clapotis, splitting an appropriate dimension 1 supersingular endomorphism. The good new is that our curves E_i will be **statically uniform**. The bad new is that computing the key exchange will require splitting a dimension 4 endomorphism, hence involves a dimension 8 isogeny, for a $\approx 32\times$ slow down.
