Computing optimal pairings on abelian varieties with theta functions

2014/01/15 - ANR Simpatic, Caen

David Lubicz, Damien Robert

## Outline

(1) Curves, pairings and cryptography
2) Abelian varieties
(3) Theta functions

4 Pairings with theta functions
(5) Performance

## The Weil pairing on elliptic curves

- Let $E: y^{2}=x^{3}+a x+b$ be an elliptic curve over a field $k$ (char $k \neq 2,3$, $4 a^{3}+27 b^{2} \neq 0$.)
- Let $P, Q \in E[\ell]$ be points of $\ell$-torsion.
- Let $f_{P}$ be a function associated to the principal divisor $\ell(P)-\ell(0)$, and $f_{Q}$ to $\ell(Q)-\ell(0)$. We define:

$$
e_{W, \ell}(P, Q)=\frac{f_{P}((Q)-(0))}{f_{Q}((P)-(0))}
$$

- The application $e_{W, \ell}: E[\ell] \times E[\ell] \rightarrow \mu_{\ell}(\bar{k})$ is a non degenerate pairing: the Weil pairing.

## Definition (Embedding degree)

The embedding degree $d$ is the smallest number such that $\ell \mid q^{d}-1 ; \mathbb{F}_{q^{d}}$ is then the smallest extension containing $\mu_{\ell}(\bar{k})$.

## The Tate pairing on elliptic curves over $\mathbb{F}_{q}$

## Definition

The Tate pairing is a non degenerate bilinear application given by

$$
\begin{aligned}
& e_{T}: E_{0}[\ell] \times E\left(\mathbb{F}_{q}\right) / \ell E\left(\mathbb{F}_{q}\right) \longrightarrow \\
&(P, Q) \longmapsto \\
& \mathbb{F}_{q^{d}}^{*} / \mathbb{F}_{q^{d}}^{*} \\
& f_{P}((Q)-(0))
\end{aligned}
$$

where

$$
E_{0}[\ell]=\left\{P \in E[\ell]\left(\mathbb{F}_{q^{d}}\right) \mid \pi(P)=[q] P\right\}
$$

- On $\mathbb{F}_{q^{d}}$, the Tate pairing is a non degenerate pairing

$$
e_{T}: E[\ell]\left(\mathbb{F}_{q^{d}}\right) \times E\left(\mathbb{F}_{q^{d}}\right) / \ell E\left(\mathbb{F}_{q^{d}}\right) \rightarrow \mathbb{F}_{q^{d}}^{*} / \mathbb{F}_{q^{d}}^{*} \simeq \mu_{\ell} ;
$$

- If $\ell^{2} \nmid E\left(\mathbb{F}_{q^{d}}\right)$ then $E\left(\mathbb{F}_{q^{d}}\right) / \ell E\left(\mathbb{F}_{q^{d}}\right) \simeq E[\ell]\left(\mathbb{F}_{q^{d}}\right)$;
- We normalise the Tate pairing by going to the power of $\left(q^{d}-1\right) / \ell$.

## Miller's functions

- We need to compute the functions $f_{P}$ and $f_{Q}$. More generally, we define the Miller's functions:

## Definition

Let $\lambda \in \mathbb{N}$ and $X \in E[\ell]$, we define $f_{\lambda, X} \in k(E)$ to be a function thus that:

$$
\left(f_{\lambda, X}\right)=\lambda(X)-([\lambda] X)-(\lambda-1)(0)
$$

- We want to compute (for instance) $f_{\ell, P}((Q)-(0))$.

## Miller's algorithm

- The key idea in Miller's algorithm is that

$$
f_{\lambda+\mu, X}=f_{\lambda, X} f_{\mu, X} f_{\lambda, \mu, X}
$$

where $\mathfrak{f}_{\lambda, \mu, X}$ is a function associated to the divisor

$$
([\lambda] X)+([\mu] X)-([\lambda+\mu] X)-(0) .
$$

- We can compute $\mathfrak{f}_{\lambda, \mu, X}$ using the addition law in $E$ : if $[\lambda] X=\left(x_{1}, y_{1}\right)$ and [ $\mu$ ] $X=\left(x_{2}, y_{2}\right)$ and $\alpha=\left(y_{1}-y_{2}\right) /\left(x_{1}-x_{2}\right)$, we have

$$
\mathfrak{f}_{\lambda, \mu, X}=\frac{y-\alpha\left(x-x_{1}\right)-y_{1}}{x+\left(x_{1}+x_{2}\right)-\alpha^{2}} .
$$

## Miller's algorithm

$$
[\lambda] X=\left(x_{1}, y_{1}\right) \quad[\mu] X=\left(x_{2}, y_{2}\right)
$$

$$
\mathfrak{f}_{\lambda, \mu, X}=\frac{y-\alpha\left(x-x_{1}\right)-y_{1}}{x+\left(x_{1}+x_{2}\right)-\alpha^{2}} .
$$

## Miller's algorithm on elliptic curves

## Algorithm (Computing the Tate pairing)

Input: $\ell \in \mathbb{N}, P=\left(x_{1}, y_{1}\right) \in E[\ell]\left(\mathbb{F}_{q}\right), Q=\left(x_{2}, y_{2}\right) \in E\left(\mathbb{F}_{q^{d}}\right)$.
Output: $\boldsymbol{e}_{T}(P, Q)$.
(1) Compute the binary decomposition: $\ell:=\sum_{i=0}^{I} b_{i} 2^{i}$. Let $T=P, f_{1}=1, f_{2}=1$.
(2) For $i$ in [I..O] compute
(1) $\alpha$, the slope of the tangent of $E$ at $T$.
(2) $T=2 T . T=\left(x_{3}, y_{3}\right)$.
(3) $f_{1}=f_{1}^{2}\left(y_{2}-\alpha\left(x_{2}-x_{3}\right)-y_{3}\right), f_{2}=f_{2}^{2}\left(x_{2}+\left(x_{1}+x_{3}\right)-\alpha^{2}\right)$.
(9) If $b_{i}=1$, then compute
(1) $\alpha$, the slope of the line going through $P$ and $T$.
(2) $T=T+Q . T=\left(x_{3}, y_{3}\right)$.
(3) $f_{1}=f_{1}^{2}\left(y_{2}-\alpha\left(x_{2}-x_{3}\right)-y_{3}\right), f_{2}=f_{2}\left(x_{2}+\left(x_{1}+x_{3}\right)-\alpha^{2}\right)$.

## Return

$$
\left(\frac{f_{1}}{f_{2}}\right)^{\frac{q^{d}-1}{\ell}}
$$

## Jacobian of curves

$C$ a smooth irreducible projective curve of genus $g$.

- Divisor: formal sum $D=\sum n_{i} P_{i}, \quad P_{i} \in C(\bar{k})$. $\operatorname{deg} D=\sum n_{i}$.
- Principal divisor: $\sum_{P \in C(\bar{k})} \nu_{P}(f) . P ; \quad f \in \bar{k}(C)$.

Jacobian of $C=$ Divisors of degree 0 modulo principal divisors

-     + Galois action
= Abelian variety of dimension $g$.
- Divisor class of a divisor $D \in \operatorname{Jac}(C)$ is generically represented by a sum of $g$ points.

## Example of Jacobians

Dimension 2: Addition law on the Jacobian of an hyperelliptic curve of genus 2:

$$
y^{2}=f(x), \operatorname{deg} f=5
$$

$$
\begin{aligned}
& D=P_{1}+P_{2}-2 \infty \\
& D^{\prime}=Q_{1}+Q_{2}-2 \infty
\end{aligned}
$$

## Example of Jacobians

Dimension 2: Addition law on the Jacobian of an hyperelliptic curve of genus 2:

$$
y^{2}=f(x), \operatorname{deg} f=5
$$

## Example of Jacobians

Dimension 2: Addition law on the Jacobian of an hyperelliptic curve of genus 2:

$$
y^{2}=f(x), \operatorname{deg} f=5
$$

## Example of Jacobians

## Dimension 3

Jacobians of hyperelliptic curves of genus 3 .
Jacobians of quartics.

## Pairings on Jacobians

- Let $P \in \operatorname{Jac}(C)[\ell]$ and $D_{P}$ a divisor on $C$ representing $P$;
- By definition of $\operatorname{Jac}(C), \ell D_{P}$ corresponds to a principal divisor $\left(f_{P}\right)$ on $C$;
- The same formulas as for elliptic curve define the Weil and Tate-Lichtenbaum pairings:

$$
\begin{gathered}
e_{W}(P, Q)=f_{P}\left(D_{Q}\right) / f_{Q}\left(D_{P}\right) \\
e_{T}(P, Q)=f_{P}\left(D_{Q}\right) .
\end{gathered}
$$

## Pairings on Jacobians

- Let $P \in \operatorname{Jac}(C)[\ell]$ and $D_{P}$ a divisor on $C$ representing $P$;
- By definition of $\operatorname{Jac}(C), \ell D_{P}$ corresponds to a principal divisor $\left(f_{P}\right)$ on $C$;
- The same formulas as for elliptic curve define the Weil and Tate-Lichtenbaum pairings:

$$
\begin{gathered}
e_{W}(P, Q)=f_{P}\left(D_{Q}\right) / f_{Q}\left(D_{P}\right) \\
e_{T}(P, Q)=f_{P}\left(D_{Q}\right) .
\end{gathered}
$$

- A key ingredient for evaluating $f_{P}\left(D_{Q}\right)$ comes from Weil reciprocity theorem.

## Theorem (Weil)

Let $D_{1}$ and $D_{2}$ be two divisors with disjoint support linearly equivalent to (0) on a smooth curve $C$. Then

$$
f_{D_{1}}\left(D_{2}\right)=f_{D_{2}}\left(D_{1}\right) .
$$

## Pairings on Jacobians

- Let $P \in \operatorname{Jac}(C)[\ell]$ and $D_{P}$ a divisor on $C$ representing $P$;
- By definition of $\operatorname{Jac}(C), \ell D_{P}$ corresponds to a principal divisor $\left(f_{P}\right)$ on $C$;
- The same formulas as for elliptic curve define the Weil and Tate-Lichtenbaum pairings:

$$
\begin{gathered}
e_{W}(P, Q)=f_{P}\left(D_{Q}\right) / f_{Q}\left(D_{P}\right) \\
e_{T}(P, Q)=f_{P}\left(D_{Q}\right) .
\end{gathered}
$$

- The extension of Miller's algorithm to Jacobians is "straightforward";
- For instance if $g=2$, the function $\mathfrak{f}_{\lambda, \mu, P}$ is of the form

$$
\frac{y-l(x)}{\left(x-x_{1}\right)\left(x-x_{2}\right)}
$$

where $l$ is of degree 3 .

## Definition

An Abelian variety is a complete connected group variety over a base field $k$.

- Abelian variety = points on a projective space (locus of homogeneous polynomials) + an abelian group law given by rational functions.

## Example

- Elliptic curves= Abelian varieties of dimension 1 ;
- If $C$ is a (smooth) curve of genus $g$, its Jacobian is an abelian variety of dimension $g$;
- In dimension $g \geqslant 4$, not every abelian variety is a Jacobian.

## Isogenies and pairings

Let $f: A \rightarrow B$ be a separable isogeny with kernel $K$ between two abelian varieties defined over $k$ :
$0 \longrightarrow K \longrightarrow 0$

- $\hat{K}$ is the Cartier dual of $K$, and we have a non degenerate pairing $e_{f}: K \times \hat{K} \rightarrow \bar{k}^{*}:$
(1) If $Q \in \hat{K}(\bar{k}), Q$ defines a divisor $D_{Q}$ on $B$;
(2) $\hat{f}(Q)=0$ means that $f^{*} D_{Q}$ is equal to a principal divisor $\left(g_{Q}\right)$ on $A$;
(3) $e_{f}(P, Q)=g_{Q}(x) / g_{Q}(x+P)$. (This last function being constant in its definition domain).
- The Weil pairing $e_{W, \ell}$ is the pairing associated to the isogeny $[\ell]: A \rightarrow A$ :

$$
e_{W, \ell}: A[\ell] \times \hat{A}[\ell] \rightarrow \mu_{\ell}(\bar{k})
$$

If $\mathscr{L}$ is an ample line bundle, the polarization $\varphi_{\mathscr{L}}$ is a morphism $A \rightarrow \widehat{A}, x \mapsto t_{x}^{*} \mathscr{L} \otimes \mathscr{L}^{-1}$.

## Definition

Let $\mathscr{L}$ be a principal polarization on $A$. The (polarized) Weil pairing $e_{W, \mathscr{L}, \ell}$ is the pairing

$$
\begin{aligned}
e_{W, \mathscr{L}, \ell}: A[\ell] \times A[\ell] & \longrightarrow \mu_{\ell}(\bar{k}) \\
(P, Q) & \longmapsto e_{W, \ell}\left(P, \varphi_{\mathscr{L}}(Q)\right)
\end{aligned}
$$

associated to the polarization $\varphi_{\mathscr{L}}$ :

$$
A \xrightarrow{[\ell]} A \xrightarrow{\mathscr{L}} \hat{A}
$$

## The Tate pairings on abelian varieties over finite fields

- From the exact sequence

$$
0 \rightarrow A[\ell]\left(\overline{\mathbb{F}}_{q^{d}}\right) \rightarrow A\left(\overline{\mathbb{F}}_{q^{d}}\right) \rightarrow^{[\ell]} A\left(\overline{\mathbb{F}}_{q^{d}}\right) \rightarrow 0
$$

we get from Galois cohomology a connecting morphism

$$
\delta: A\left(\mathbb{F}_{q^{d}}\right) / \ell A\left(\mathbb{F}_{q^{d}}\right) \rightarrow H^{1}\left(\operatorname{Gal}\left(\overline{\mathbb{F}}_{q^{d}} / \mathbb{F}_{q^{d}}\right), A[\ell]\right) ;
$$

- Composing with the Weil pairing, we get a bilinear application

$$
A[\ell]\left(\mathbb{F}_{q^{d}}\right) \times A\left(\mathbb{F}_{q^{d}}\right) / \ell A\left(\mathbb{F}_{q^{d}}\right) \rightarrow H^{1}\left(\operatorname{Gal}\left(\overline{\mathbb{F}}_{q^{d}} / \mathbb{F}_{q^{d}}\right), \mu_{\ell}\right) \simeq \mathbb{F}_{q^{d}}^{*} / \mathbb{F}_{q^{d}}^{*} \simeq \mu_{\ell}
$$

where the last isomorphism comes from the Kummer sequence

$$
1 \rightarrow \mu_{\ell} \rightarrow \overline{\mathbb{F}}_{q^{d}}^{*} \rightarrow \overline{\mathbb{F}}_{q^{d}}^{*} \rightarrow 1
$$

and Hilbert 90;

- Explicitely, if $P \in A[\ell]\left(\mathbb{F}_{q^{d}}\right)$ and $Q \in A\left(\mathbb{F}_{q^{d}}\right)$ then the (reduced) Tate pairing is given by

$$
e_{T}(P, Q)=e_{W}\left(P, \pi\left(Q_{0}\right)-Q_{0}\right)
$$

where $Q_{0}$ is any point such that $Q=[\ell] Q_{0}$ and $\pi$ is the Frobenius of $\mathbb{F}_{q^{d}}$.

- Let $(A, \mathscr{L})$ be a principally polarized abelian variety;
- To a degree 0 cycle $\sum n_{i}\left(P_{i}\right)$ on $A$, we can associate the divisor $\sum t_{P_{i}^{*}} \mathscr{L}^{n_{i}}$ on $A$;
- The cycle $\sum n_{i}\left(P_{i}\right)$ corresponds to a trivial divisor iff $\sum n_{i} P_{i}=0$ in $A$;
- If $f$ is a function on $A$ and $D=\sum\left(P_{i}\right)$ a cycle whose support does not contain a zero or pole of $f$, we let

$$
f(D)=\prod f\left(P_{i}\right)^{n_{i}} .
$$

(In the following, when we write $f(D)$ we will always assume that we are in this situation.)

## Theorem ([Lan58])

Let $D_{1}$ and $D_{2}$ be two cycles equivalent to 0 , and $f_{D_{1}}$ and $f_{D_{2}}$ be the corresponding functions on $A$. Then

$$
f_{D_{1}}\left(D_{2}\right)=f_{D_{2}}\left(D_{1}\right)
$$

## The Weil and Tate pairings on abelian varieties

## Theorem

Let $P, Q \in A[\ell]$. Let $D_{P}$ and $D_{Q}$ be two cycles equivalent to $(P)-(0)$ and $(Q)-(0)$. The Weil pairing is given by

$$
e_{W}(P, Q)=\frac{f_{\ell D_{P}}\left(D_{Q}\right)}{f_{\ell D_{Q}}\left(D_{P}\right)}
$$

## Theorem

Let $P \in A[\ell]\left(\mathbb{F}_{q^{d}}\right)$ and $Q \in A\left(\mathbb{F}_{q^{d}}\right)$, and let $D_{P}$ and $D_{Q}$ be two cycles equivalent to $(P)-(0)$ and $(Q)-(0)$. The (non reduced) Tate pairing is given by

$$
e_{T}(P, Q)=f_{\ell D_{P}}\left(D_{Q}\right)
$$

- The moduli space of abelian varieties of dimension $g$ is a space of dimension $g(g+1) / 2$. We have more liberty to find optimal abelian varieties in function of the security parameters.
- Supersingular abelian varieties can have larger embedding degree than supersingular elliptic curves.
- Over a Jacobian, we can use twists even if they are not coming from twists of the underlying curve.
- If $A$ is an abelian variety of dimension $g, A[\ell]$ is a $(\mathbb{Z} / \ell \mathbb{Z})$-module of dimension $2 g \Rightarrow$ the structure of pairings on abelian varieties is richer.
- A complex abelian variety is of the form $A=V / \Lambda$ where $V \simeq \mathbb{C}^{g}$ is a $\mathbb{C}$-vector space and $\Lambda$ a lattice, with a polarization (actually an ample line bundle) $\mathscr{L}$ on it;
- The Chern class of $\mathscr{L}$ corresponds to a symplectic real form $E$ on $V$ such that $E(i x, i y)=E(x, y)$ and $E(\Lambda, \Lambda) \subset \mathbb{Z}$;
- The commutator pairing $e_{\mathscr{L}}$ is then given by $\exp (2 i \pi E(\cdot, \cdot))$;
- A principal polarization on $A$ corresponds to a decomposition $\Lambda=\Omega \mathbb{Z}^{g}+\mathbb{Z}^{g}$ with $\Omega \in \mathfrak{H}_{g}$ the Siegel space;
- The associated Riemann form on $A$ is then given by

$$
E\left(\Omega x_{1}+x_{2}, \Omega y_{1}+y_{2}\right)={ }^{t} x_{1} \cdot y_{2}-{ }^{t} y_{1} \cdot x_{2} .
$$

- The theta functions of level $n$ give a system of projective coordinates:

$$
\vartheta\left[{ }_{b}^{a}\right](z, \Omega)=\sum_{n \in \mathbb{Z} g} e^{\pi i^{t}(n+a)(n+a)+2 \pi i^{t}(n+a)(z+b)} \quad a, b \in \mathbb{Q}^{g}
$$

- If $n=2$, we get (in the generic case) an embedding of the Kummer variety $A / \pm 1$.

## Remark

Working on level $n$ mean we take a $n$-th power of the principal polarization. So in the following we will compute the $n$-th power of the usual Weil and Tate pairings.

## The differential addition law $(k=\mathbb{C})$

$$
\begin{aligned}
&\left(\sum_{t \in Z(\overline{2})} \chi(t) \vartheta_{i+t}(x+y) \vartheta_{j+t}(x-y)\right) \cdot\left(\sum_{t \in Z(\overline{2})} \chi(t) \vartheta_{k+t}(0) \vartheta_{l+t}(0)\right)= \\
&\left(\sum_{t \in Z(\overline{2})} \chi(t) \vartheta_{-i^{\prime}+t}(y) \vartheta_{j^{\prime}+t}(y)\right) \cdot\left(\sum_{t \in Z(\overline{2})} \chi(t) \vartheta_{k^{\prime}+t}(x) \vartheta_{l^{\prime}+t}(x)\right) .
\end{aligned}
$$

where $\quad \chi \in \hat{Z}(\overline{2}), i, j, k, l \in Z(\bar{n})$

$$
\begin{aligned}
& \left(i^{\prime}, j^{\prime}, k^{\prime}, l^{\prime}\right)=A(i, j, k, l) \\
& A=\frac{1}{2}\left(\begin{array}{cccc}
1 & 1 & 1 & 1 \\
1 & 1 & -1 & -1 \\
1 & -1 & 1 & -1 \\
1 & -1 & -1 & 1
\end{array}\right)
\end{aligned}
$$

## Example: differential addition in dimension 1 and in level 2

## Algorithm

$$
\begin{aligned}
\text { Input } & z_{P}=\left(x_{0}, x_{1}\right), z_{Q}=\left(y_{0}, y_{1}\right) \text { and } z_{P-Q}=\left(z_{0}, z_{1}\right) \text { with } z_{0} z_{1} \neq 0 ; \\
& z_{0}=(a, b) \text { and } A=2\left(a^{2}+b^{2}\right), B=2\left(a^{2}-b^{2}\right) .
\end{aligned}
$$

Output $z_{P+Q}=\left(t_{0}, t_{1}\right)$.
(1) $t_{0}^{\prime}=\left(x_{0}^{2}+x_{1}^{2}\right)\left(y_{0}^{2}+y_{2}^{2}\right) / A$
(2) $t_{1}^{\prime}=\left(x_{0}^{2}-x_{1}^{2}\right)\left(y_{0}^{2}-y_{1}^{2}\right) / B$
(3) $t_{0}=\left(t_{0}^{\prime}+t_{1}^{\prime}\right) / z_{0}$
(9) $t_{1}=\left(t_{0}^{\prime}-t_{1}^{\prime}\right) / z_{1}$

Return $\left(t_{0}, t_{1}\right)$

## Cost of the arithmetic with low level theta functions (char $k \neq 2$ )

|  | Montgomery | Level 2 | Jacobians coordinates |
| :--- | :---: | :---: | :---: |
| Doubling | $5 M+4 S+1 m_{0}$ | $3 M+6 S+3 m_{0}$ | $3 M+5 S$ |
| Mixed Addition |  |  | $7 M+6 S+1 m_{0}$ |

Multiplication cost in genus 1 (one step).

|  | Mumford | Level 2 | Level 4 |
| :--- | :---: | :---: | :---: |
| Doubling | $34 M+7 S$ |  |  |
| Mixed Addition | $37 M+6 S$ | $7 M+12 S+9 m_{0}$ | $49 M+36 S+27 m_{0}$ |

Multiplication cost in genus 2 (one step).

## Miller functions with theta coordinates

## Proposition (Lubicz-R. [LR13])

- For $P \in A$ we note $z_{P}$ a lift to $\mathbb{C}^{g}$. We call $P$ a projective point and $z_{P}$ an affine point (because we describe them via their projective, resp affine, theta coordinates);
- We have (up to a constant)

$$
f_{\lambda, P}(z)=\frac{\vartheta(z)}{\vartheta\left(z+\lambda z_{P}\right)}\left(\frac{\vartheta\left(z+z_{P}\right)}{\vartheta(z)}\right)^{\lambda}
$$

- So (up to a constant)

$$
\mathfrak{f}_{\lambda, \mu, P}(z)=\frac{\vartheta\left(z+\lambda z_{P}\right) \vartheta\left(z+\mu z_{P}\right)}{\vartheta(z) \vartheta\left(z+(\lambda+\mu) z_{P}\right)} .
$$

## Three way addition

## Proposition (Lubicz-R. [LR13])

From the affine points $z_{P}, z_{Q}, z_{R}, z_{P+Q}, z_{P+R}$ and $z_{Q+R}$ one can compute the affine point $z_{P+Q+R}$.
(In level 2, the proposition is only valid for "generic" points).

## Proof.

We can compute the three way addition using a generalised version of Riemann's relations:

$$
\begin{aligned}
\left(\sum_{t \in Z(\overline{2})} \chi(t) \vartheta_{i+t}\right. & \left.\left(z_{P+Q+R}\right) \vartheta_{j+t}\left(z_{P}\right)\right) \cdot\left(\sum_{t \in Z(\overline{2})} \chi(t) \vartheta_{k+t}\left(z_{Q}\right) \vartheta_{l+t}\left(z_{R}\right)\right)= \\
& \left(\sum_{t \in Z \overline{(2)}} \chi(t) \vartheta_{-i^{\prime}+t}\left(z_{0}\right) \vartheta_{j^{\prime}+t}\left(z_{Q+R}\right)\right) \cdot\left(\sum_{t \in Z(\overline{2})} \chi(t) \vartheta_{k^{\prime}+t}\left(z_{P+R}\right) \vartheta_{l^{\prime}+t}\left(z_{P+Q}\right)\right) .
\end{aligned}
$$

## Three way addition in dimension 1 level 2

## Algorithm

Input The points $x, y, z, X=y+z, Y=x+z, Z=x+y ;$
Output $T=x+y+z$.
Return

$$
\begin{aligned}
& T_{0}=\frac{\left(a X_{0}+b X_{1}\right)\left(Y_{0} Z_{0}+Y_{1} Z_{1}\right)}{x_{0}\left(y_{0} z_{0}+y_{1} z_{1}\right)}+\frac{\left(a X_{0}-b X_{1}\right)\left(Y_{0} Z_{0}-Y_{1} Z_{1}\right)}{x_{0}\left(y_{0} z_{0}-y_{1} z_{1}\right)} \\
& T_{1}=\frac{\left(a X_{0}+b X_{1}\right)\left(Y_{0} Z_{0}+Y_{1} Z_{1}\right)}{x_{1}\left(y_{0} z_{0}+y_{1} z_{1}\right)}-\frac{\left(a X_{0}-b X_{1}\right)\left(Y_{0} Z_{0}-Y_{1} Z_{1}\right)}{x_{1}\left(y_{0} z_{0}-y_{1} z_{1}\right)}
\end{aligned}
$$

## Computing the Miller function $\mathfrak{f}_{\lambda, \mu, P}((Q)-(0))$

## Algorithm

Input $\lambda P, \mu P$ and $Q$;
Output $\mathfrak{f}_{\lambda, \mu, P}((Q)-(0))$
(1) Compute $(\lambda+\mu) P, Q+\lambda P, Q+\mu P$ using normal additions and take any affine lifts $z_{(\lambda+\mu) P}, z_{Q+\lambda P}$ and $z_{Q+\mu P}$;
(2) Use a three way addition to compute $z_{Q+(\lambda+\mu) P}$;

Return

$$
\mathfrak{f}_{\lambda, \mu, P}((Q)-(0))=\frac{\vartheta\left(z_{Q}+\lambda z_{P}\right) \vartheta\left(z_{Q}+\mu z_{P}\right)}{\vartheta\left(z_{Q}\right) \vartheta\left(z_{Q}+(\lambda+\mu) z_{P}\right)} \cdot \frac{\vartheta\left((\lambda+\mu) z_{P}\right) \vartheta\left(z_{P}\right)}{\vartheta\left(\lambda z_{P}\right) \vartheta\left(\mu z_{P}\right)}
$$

## Lemma

The result does not depend on the choice of affine lifts in Step 2.
() This allows us to evaluate the Weil and Tate pairings and derived pairings;
(3) Not possible a priori to apply this algorithm in level 2.

## The Tate pairing with Miller's functions and theta coordinates

- Let $P \in A[\ell]\left(\mathbb{F}_{q^{d}}\right)$ and $Q \in A\left(\mathbb{F}_{q^{d}}\right)$; choose any lift $z_{P}, z_{Q}$ and $z_{P+Q}$.
- The algorithm loop over the binary expansion of $\ell$, and at each step does a doubling step, and if necessary an addition step.

Given $z_{\lambda P}, z_{\lambda P+Q}$;
Doubling Compute $z_{2 \lambda P}, z_{2 \lambda P+Q}$ using two differential additions; Addition Compute $(2 \lambda+1) P$ and take an arbitrary lift $z_{(2 \lambda+1) P}$. Use a three way addition to compute $z_{(2 \lambda+1) P+Q}$.

- At the end we have computed affine points $z_{\ell P}$ and $z_{\ell P+Q}$. Evaluating the Miller function then gives exactly the quotient of the projective factors between $z_{\ell P}, z_{0}$ and $z_{\ell P+Q}, z_{Q}$.
() Described this way can be extended to level 2 by using compatible additions;
(:) Three way additions and normal (or compatible) additions are quite cumbersome, is there a way to only use differential additions?

## The Weil and Tate pairing with theta coordinates (Lubicz-R. [LR10])

Using directly the formula for $f_{\ell, p}(z)$ we get that the Weil and Tate pairings are given by

$$
\begin{gathered}
e_{W, \ell}(P, Q)=\frac{\vartheta\left(z_{Q}+\ell z_{P}\right) \vartheta(0)}{\vartheta\left(z_{Q}\right) \vartheta\left(\ell z_{P}\right)} \frac{\vartheta\left(z_{P}\right) \vartheta\left(\ell z_{Q}\right)}{\vartheta\left(z_{P}+\ell z_{Q}\right) \vartheta(0)} \\
e_{T, \ell}(P, Q)=\frac{\vartheta\left(z_{Q}+\ell z_{P}\right) \vartheta(0)}{\vartheta\left(z_{Q}\right) \vartheta\left(\ell z_{P}\right)}
\end{gathered}
$$

## The Weil and Tate pairing with theta coordinates (Lubicz-R. [LR10])

$P$ and $Q$ points of $\ell$-torsion.

$$
\begin{array}{ccccc}
z_{0} & z_{P} & 2 z_{P} & \ldots & \ell z_{P}=\lambda_{P}^{0} z_{0} \\
z_{Q} & z_{P} \oplus z_{Q} & 2 z_{P}+z_{Q} & \ldots & \ell z_{P}+z_{Q}=\lambda_{P}^{1} z_{Q} \\
2 z_{Q} & z_{P}+2 z_{Q} & & & \\
\ldots & \ldots & & & \\
\ell Q=\lambda_{Q}^{0} 0_{A} & z_{P}+\ell z_{Q}=\lambda_{Q}^{1} z_{P} & & & \\
\text { - } e_{W, \ell}(P, Q)=\frac{\lambda_{P}^{1} \lambda_{Q}^{0}}{\lambda_{P}^{0} \lambda_{Q}^{1}} . \\
\text { - } e_{T, \ell}(P, Q)=\frac{\lambda_{p}^{1}}{\lambda_{P}^{0}} .
\end{array}
$$

## Why does it work?

$$
\begin{array}{ccccc}
z_{0} & \alpha z_{P} & \alpha^{4}\left(2 z_{P}\right) & \ldots & \alpha^{\ell^{2}}\left(\ell z_{P}\right)=\lambda^{\prime 0} z_{0} \\
\beta z_{Q} & \gamma\left(z_{P} \oplus z_{Q}\right) & \frac{r^{2} \alpha^{2}}{\beta}\left(2 z_{P}+z_{Q}\right) & \ldots & \frac{r^{\ell} \alpha^{\ell(\ell-1)}}{\beta^{\ell-1}}\left(\ell z_{P}+z_{Q}\right)=\lambda^{\prime 1} \beta z_{Q} \\
\beta^{4}\left(2 z_{Q}\right) & \frac{\gamma^{2} \beta^{2}}{\alpha}\left(z_{P}+2 z_{Q}\right) & & & \\
\ldots & \ldots & & \\
\beta^{\ell^{2}}\left(\ell z_{Q}\right)=\lambda_{Q}^{\prime 0} z_{0} & \frac{\gamma^{\ell} \beta^{\ell(\ell-1)}}{\alpha^{\ell-1}}\left(z_{P}+\ell z_{Q}\right)=\lambda_{Q}^{\prime 1} \alpha z_{P} & &
\end{array}
$$

We then have

$$
\begin{gathered}
\lambda_{P}^{\prime 0}=\alpha^{\ell^{2}} \lambda_{P}^{0}, \quad \lambda_{Q}^{\prime 0}=\beta^{\ell^{2}} \lambda_{Q}^{0}, \quad \lambda_{P}^{\prime 1}=\frac{\gamma^{\ell} \alpha^{(\ell(\ell-1)}}{\beta^{\ell}} \lambda_{P}^{1}, \quad \lambda_{Q}^{\prime 1}=\frac{\gamma^{\ell} \beta^{(\ell(\ell-1)}}{\alpha^{\ell}} \lambda_{Q}^{1} \\
e_{W, \ell}^{\prime}(P, Q)=\frac{\lambda_{P}^{\prime 1} \lambda_{Q}^{\prime 0}}{\lambda_{P}^{\prime 0} \lambda_{Q}^{\prime 1}}=\frac{\lambda_{P}^{1} \lambda_{Q}^{0}}{\lambda_{P}^{0} \lambda_{Q}^{1}}=e_{W, \ell}(P, Q) \\
e_{T, \ell}^{\prime}(P, Q)=\frac{\lambda_{P}^{\prime 1}}{\lambda_{P}^{0}}=\frac{\gamma^{\ell}}{\alpha^{\ell} \beta^{\ell}} \frac{\lambda_{P}^{1}}{\lambda_{P}^{0}}=\frac{\gamma^{\ell}}{\alpha^{\ell} \beta^{\ell}} e_{T, \ell}(P, Q) .
\end{gathered}
$$

- If $n=2$ we work over the Kummer variety $K$ over $k$, so $e(P, Q) \in \vec{k}^{*, \pm 1}$.
- We represent a class $x \in \bar{k}^{*, \pm 1}$ by $x+1 / x \in \bar{k}^{*}$. We want to compute the symmetric pairing

$$
e_{s}(P, Q)=e(P, Q)+e(-P, Q) .
$$

- From $\pm P$ and $\pm Q$ we can compute $\{ \pm(P+Q), \pm(P-Q)\}$ (need a square root), and from these points the symmetric pairing.
- $e_{s}$ is compatible with the $\mathbb{Z}$-structure on $K$ and $\bar{k}^{*, \pm 1}$.
- The $\mathbb{Z}$-structure on $\bar{k}^{* \pm}$ can be computed as follow:

$$
\left(x^{\ell_{1}+\ell_{2}}+\frac{1}{x^{\ell_{1}+\ell_{2}}}\right)+\left(x^{\ell_{1}-\ell_{2}}+\frac{1}{x^{\ell_{1}-\ell_{2}}}\right)=\left(x^{\ell_{1}}+\frac{1}{x^{\ell_{1}}}\right)\left(x^{\ell_{2}}+\frac{1}{x^{\ell_{2}}}\right)
$$

## Ate pairing

- Let $P \in G_{2}=A[\ell] \bigcap \operatorname{Ker}\left(\pi_{q}-[q]\right)$ and $Q \in G_{1}=A[\ell] \bigcap \operatorname{Ker}\left(\pi_{q}-1\right) ; \lambda \equiv q$ $\bmod \ell$.
- In projective coordinates, we have $\pi_{q}^{d}(P+Q)=\lambda^{d} P+Q=P+Q$;
- Of course, in affine coordinates, $\pi_{q}^{d}\left(z_{P+Q}\right) \neq \lambda^{d} z_{P}+z_{Q}$.
- But if $\pi_{q}\left(z_{P+Q}\right)=C *\left(\lambda z_{P}+z_{Q}\right)$, then $C$ is exactly the (non reduced) ate pairing (up to a renormalisation)!

## Algorithm (Computing the ate pairing)

$$
\text { Input } P \in G_{2}, Q \in G_{1} \text {; }
$$

(1) Compute $z_{Q}+\lambda z_{P}, \lambda z_{P}$ using differential additions;
(2) Find the projective factors $C_{1}$ and $C_{0}$ such that $z_{Q}+\lambda z_{P}=C_{1} * \pi\left(z_{P+Q}\right)$ and $\lambda z_{P}=C_{0} * \pi\left(z_{P}\right)$ respectively;
Return $\left(C_{1} / C_{0}\right)^{\frac{q^{d}-1}{l}}$.

## Optimal ate pairing

- Let $\lambda=m \ell=\sum c_{i} q^{i}$ be a multiple of $\ell$ with small coefficients $c_{i}$. $(\ell \nmid m)$
- The pairing

$$
\begin{aligned}
a_{\lambda}: G_{2} \times G_{1} & \longrightarrow \mu_{\ell} \\
(P, Q) & \longmapsto\left(\prod_{i} f_{c_{i}, P}(Q)^{q^{i}} \prod_{i} f_{\sum_{j>i} c_{j} q^{j}, c_{i} q^{i}, P}(Q)\right)^{\left(q^{d}-1\right) / \ell}
\end{aligned}
$$

is non degenerate when $m d q^{d-1} \not \equiv\left(q^{d}-1\right) / r \sum_{i} i c_{i} q^{i-1} \bmod \ell$.

- Since $\varphi_{d}(q)=0 \bmod \ell$ we look at powers $q, q^{2}, \ldots, q^{\varphi(d)-1}$.
- We can expect to find $\lambda$ such that $c_{i} \approx \ell^{1 / \varphi(d)}$.

## Optimal ate pairing with theta functions

## Algorithm (Computing the optimal ate pairing)

$$
\text { Input } \pi_{q}(P)=[q] P, \pi_{q}(Q)=Q, \lambda=m \ell=\sum c_{i} q^{i} \text {; }
$$

(1) Compute the $z_{Q}+c_{i} z_{P}$ and $c_{i} z_{P}$;
(2) Apply Frobeniuses to obtain the $z_{Q}+c_{i} q^{i} z_{p}, c_{i} q^{i} z_{p}$;
(0. Compute $c_{i} q^{i} z_{p} \oplus \sum_{j} c_{j} q^{j} z_{p}$ (up to a constant) and then do a three way addition to compute $z_{Q}+c_{i} q^{i} z_{P}+\sum_{j} c_{j} q^{j} z_{P}$ (up to the same constant);
(- Recurse until we get $\lambda z_{P}=C_{0} * z_{P}$ and $z_{Q}+\lambda z_{P}=C_{1} * z_{Q}$;
Return $\left(C_{1} / C_{0}\right)^{q^{d}-1}$.

- Computing $c_{i} q^{i} z_{P} \pm \sum_{j} c_{j} q^{j} z_{P}$ requires a square root (very costly);
- And we need to recognize $c_{i} q^{i} z_{P}+\sum_{j} c_{j} q^{j} z_{P}$ from $c_{i} q^{i} z_{P}-\sum_{j} c_{j} q^{j} z_{P}$.
- We will use compatible additions: if we know $x, y, z$ and $x+z, y+z$, we can compute $x+y$ without a square root;
- We apply the compatible additions with $x=c_{i} q^{i} z_{p}, y=\sum_{j} c_{j} q^{j} z_{p}$ and $z=z_{Q}$.

## Compatible additions

- Recall that we know $x, y, z$ and $x+z, y+z$;
- From it we can compute $(x+z) \pm(y+z)=\{x+y+2 z, x-y\}$ and of course $\{x+y, x-y\}$;
- Then $x+y$ is the element in $\{x+y, x-y\}$ not appearing in the preceding set;
- Since $x-y$ is a common point, we can recover it without computing a square root.

## The compatible addition algorithm in dimension 1

## Algorithm

$$
\text { Input } x, y, Y=x+z, X=y+z
$$

(1) Computing $x \pm y$ :

$$
\begin{gathered}
\alpha=\left(x_{0}^{2}+x_{1}^{2}\right)\left(y_{0}^{2}+y_{1}^{2}\right) / A \\
\beta=\left(x_{0}^{2}-x_{1}^{2}\right)\left(y_{0}^{2}-y_{1}^{2}\right) / B \\
\kappa_{00}=(\alpha+\beta), \kappa_{11}=(\alpha-\beta) \\
\kappa_{10}:=x_{0} x_{1} y_{0} y_{1} / a b
\end{gathered}
$$

(2) Computing $(x+z) \pm(y+z)$ :

$$
\begin{gathered}
\alpha^{\prime}=\left(Y_{0}^{2}+Y_{1}^{2}\right)\left(X_{0}^{2}+X_{1}^{2}\right) / A \\
\beta^{\prime}=\left(Y_{0}^{2}-Y_{1}^{2}\right)\left(X_{0}^{2}-X_{1}^{2}\right) / B \\
\kappa_{00}^{\prime}=\alpha^{\prime}+\beta^{\prime}, \kappa_{11}^{\prime}=\alpha^{\prime}-\beta^{\prime} \\
\kappa_{10}^{\prime}=Y_{1} Y_{2} X_{1} X_{2} / a b
\end{gathered}
$$

Return $x+y=\left[\kappa_{00}\left(\kappa_{10} \kappa_{00}^{\prime}-\kappa_{10}^{\prime} \kappa_{00}\right), \kappa_{10}\left(\kappa_{10} \kappa_{00}^{\prime}-\kappa_{10}^{\prime} \kappa_{00}\right)+\kappa_{00}\left(\kappa_{11} \kappa_{00}^{\prime}-\kappa_{11}^{\prime} \kappa_{00}\right)\right]$

## One step of the pairing computation

## Algorithm (A step of the Miller loop with differential additions)

$$
\text { Input } n P=\left(x_{n}, z_{n}\right) ;(n+1) P=\left(x_{n+1}, z_{n+1}\right),(n+1) P+Q=\left(x_{n+1}^{\prime}, z_{n+1}^{\prime}\right)
$$

Output $2 n P=\left(x_{2 n}, z_{2 n}\right) ;(2 n+1) P=\left(x_{2 n+1}, z_{2 n+1}\right)$;

$$
(2 n+1) P+Q=\left(x_{2 n+1}^{\prime}, z_{2 n+1}^{\prime}\right)
$$

(1) $\alpha=\left(x_{n}^{2}+z_{n}^{2}\right) ; \beta=\frac{A}{B}\left(x_{n}^{2}-z_{n}^{2}\right)$.
(2) $X_{n}=\alpha^{2} ; X_{n+1}=\alpha\left(x_{n+1}^{2}+z_{n+1}^{2}\right) ; X_{n+1}^{\prime}=\alpha\left(x_{n+1}^{\prime 2}+z_{n+1}^{\prime 2}\right)$;
(3) $Z_{n}=\beta\left(x_{n}^{2}-z_{n}^{2}\right) ; Z_{n+1}=\beta\left(x_{n+1}^{2}-z_{n+1}^{2}\right) ; Z_{n+1}^{\prime}=\beta\left(x_{n+1}^{\prime 2}+z_{n+1}^{\prime 2}\right)$;
(4) $x_{2 n}=X_{n}+Z_{n} ; x_{2 n+1}=\left(X_{n+1}+Z_{n+1}\right) / x_{P} ; x_{2 n+1}^{\prime}=\left(X_{n+1}^{\prime}+Z_{n+1}^{\prime}\right) / x_{Q}$;
(5) $z_{2 n}=\frac{a}{b}\left(X_{n}-Z_{n}\right) ; z_{2 n+1}=\left(X_{n+1}-Z_{n+1}\right) / z_{p} ; z_{2 n+1}^{\prime}=\left(X_{n+1}^{\prime}-Z_{n+1}^{\prime}\right) / z_{Q}$;

Return $\left(x_{2 n}, z_{2 n}\right) ;\left(x_{2 n+1}, z_{2 n+1}\right) ;\left(x_{2 n+1}^{\prime}, z_{2 n+1}^{\prime}\right)$.

$$
\begin{array}{ll}
g=1 & 4 \mathbf{M}+2 \mathbf{m}+8 \mathbf{S}+3 m_{0} \\
g=2 & 8 \mathbf{M}+6 \mathbf{m}+16 \mathbf{S}+9 \mathrm{~m}_{0}
\end{array}
$$

Tate pairing with theta coordinates, $P, Q \in A[\ell]\left(\mathbb{F}_{q^{d}}\right)$ (one step)

Operations in $\mathbb{F}_{q}: M$ : multiplication, $S$ : square, $m$ multiplication by a coordinate of $P$ or $Q, m_{0}$ multiplication by a theta constant;
Mixed operations in $\mathbb{F}_{q}$ and $\mathbb{F}_{q^{d}}: M, m$ and $m_{0}$;
Operations in $\mathbb{F}_{q^{d}}: \mathbf{M}, \mathbf{m}$ and $\mathbf{S}$.

## Remark

- Doubling step for a Miller loop with Edwards coordinates: $9 \mathbf{M}+7 \mathbf{S}+2 m_{0}$;
- Just doubling a point in Mumford projective coordinates using the fastest algorithm [Lan05]: 33M $+7 \mathbf{S}+1 \mathrm{~m}_{0}$;
- Asymptotically the final exponentiation is more expensive than Miller's loop, so the Weil's pairing is faster than the Tate's pairing!

$$
\begin{array}{ll}
g=1 & 1 \mathbf{m}+2 \mathbf{S}+2 \mathrm{M}+2 M+1 m+6 S+3 m_{0} \\
g=2 & 3 \mathbf{m}+4 \mathbf{S}+4 \mathrm{M}+4 M+3 m+12 S+9 m_{0} \\
\hline
\end{array}
$$

Tate pairing with theta coordinates, $P \in A[\ell]\left(\mathbb{F}_{q}\right), Q \in A[\ell]\left(\mathbb{F}_{q^{d}}\right)$ (one step)

## Ate and optimal ate pairings

$$
\begin{array}{ll}
g=1 & 4 \mathbf{M}+1 \mathbf{m}+8 \mathbf{S}+1 \mathbf{m}+3 \mathrm{~m}_{0} \\
g=2 & 8 \mathbf{M}+3 \mathbf{m}+16 \mathbf{S}+3 \mathrm{~m}+9 \mathrm{~m}_{0} \\
\hline
\end{array}
$$

Ate pairing with theta coordinates, $P \in G_{2}, Q \in G_{1}$ (one step)

## Remark

Using affine Mumford coordinates in dimension 2, the hyperelliptic ate pairing costs [Gra+07]:

Doubling $1 \mathbf{I}+29 \mathbf{M}+9 \mathbf{S}+7 \mathrm{M}$
Addition $\mathbf{1 I}+29 \mathbf{M}+5 \mathbf{S}+7 \mathbf{M}$
(where $\mathbf{I}$ denotes the cost of an affine inversion in $\mathbb{F}_{q^{d}}$ ).
